4.91.1 Detailed Description

Contains the functions that deal with the rewriting and manipulation of expressions/terms in polynomial representation.

Definition in file notation.c.

4.91.2 Function Documentation

4.91.2.1 NormPolyTerm()

```
int NormPolyTerm (
            PHEAD WORD * term )
```

Definition at line 53 of file notation.c.

4.91.2.2 ConvertToPoly()

```
int ConvertToPoly (
            PHEAD WORD * term,
            WORD * outterm,
            WORD * comlist,
            WORD par )
```

Definition at line 309 of file notation.c.

4.91.2.3 LocalConvertToPoly()

```
int LocalConvertToPoly (
            PHEAD WORD * term,
            WORD * outterm,
            WORD startebuf,
            WORD par )
```

Converts a generic term to polynomial notation in which there are only symbols and brackets. During conversion there will be only symbols. Brackets are stripped. Objects that need 'translation' are put inside a special compiler buffer and represented by a symbol. The numbering of the extra symbols is down from the maximum. In principle there can be a problem when running into the already assigned ones. This uses the FindTree for searching in the global tree and then looks further in the AT.ebufnum. This allows fully parallel processing. Hence we need no locks. Cannot be used in the same module as ConvertToPoly.

Definition at line 514 of file notation.c.

Referenced by poly_factorize_expression().

4.91.2.4 ConvertFromPoly()

```
int ConvertFromPoly (
            PHEAD WORD * term,
            WORD * outterm,
            WORD from,
            WORD to,
            WORD offset,
            WORD par )
```

Definition at line 664 of file notation.c.

4.91.2.5 FindSubterm()

```
int FindSubterm (
            WORD * subterm )
```

Definition at line 777 of file notation.c.

4.91.2.6 FindLocalSubterm()

```
int FindLocalSubterm (
            PHEAD WORD * subterm,
            WORD startebuf )
```

Definition at line 847 of file notation.c.

4.91.2.7 PrintSubtermList()

```
void PrintSubtermList (
            int from,
            int to )
```

Definition at line 901 of file notation.c.

4.91.2.8 PrintExtraSymbol()

```
void PrintExtraSymbol (
            int num,
            WORD * terms,
            int par )
```

Definition at line 1013 of file notation.c.

4.91.2.9 FindSubexpression()

```
int FindSubexpression (
            WORD * subexpr )
```

Definition at line 1100 of file notation.c.

4.91.2.10 ExtraSymFun()

```
int ExtraSymFun (
            PHEAD WORD * term,
            WORD level )
```

Definition at line 1153 of file notation.c.

4.91.2.11 PruneExtraSymbols()

```
int PruneExtraSymbols (
            WORD downto )
```

Definition at line 1221 of file notation.c.

00044         This routine knows objects of the following types:
00045             SYMBOL
00046             HAAKJE
00047             SNUMBER
00048             LNUMBER
00049         The SNUMBER and LNUMBER are worked into the coefficient.
00050         One of the essences here is that everything can be done in place.

4.93.1 Detailed Description

Contains the 'operations' These are the trace routines, the contractions of the Levi-Civita tensors and the tensor to vector/vector to tensor routines. The trace and contraction routines are done in a special way (see commentary with the FIXEDGLOBALS struct)

```

```
00390         #[ Trace4no :           WORD Trace4no(number,kron,t)
00391
00392         Takes the trace of a string of gamma matrices in 4 dimensions.
00393         There is no test for indices or vectors that are the same.
00394         The four dimensions refer to the contraction in the algebra:
00395         g_(i,a,b,c) = e_(a,b,c,d)*g_(i,5_,d) + g_(i,a)*d_(b,c)
00396                     - g_(i,b)*d_(a,c) + g_(i,c)*d_(a,b)
00397         This simplifies life very much and leads to shorter expressions
00398         than in the n dimensional case.
00399
00400         Parameters:
00401         number: the number of vectors/indices in inlist.
00402         inlist: the indices/vectors in the string.
00403         kron:   the output delta's.
00404         gamma5: the potential gamma5 in front.
00405         t:      the struct for scratch manipulations.
00406         stack:  the space to put all scratch arrays in.
00407
00408         The return value is zero if there are no more terms, 1 if a
00409         term was generated with a positive sign and -1 if a term was
00410         generated with a negative sign.
00411         The value of one is increased to two if the first 4 values
00412         in kron should be interpreted as a Levi-Civita tensor.
00413
00414         Note that kron should have more places reserved than the number
00415         of indices in inlist, because it will contain dummy indices
00416         temporarily. In principle there can be 'number*1/4' extra dummies.

00669         #] Trace4no :
00670         #[ Trace4 :             WORD Trace4(term,params,num,level)
00671
00672         Generates traces of the string of gamma matrices in 'instring'.
00673
00674         The difference with the routine tracen ( for n dimensions )
00675         lies in the treatment of gamma 5 and the specific form
00676         of the Chisholm identities. The identities used here are
00677         g(mu)*g(a1)*...*g(an)*g(mu)=
00678         n=odd:  -2*g(an)*...*g(a1)    ( reversed order )
00679         n=even: 2*g(an)*g(a1)*...*g(a(n-1))
00680             +2*g(a(n-1))*...*g(a1)*g(an)
00681         There is a special case for n=2 : 4*d(a1,a2)*gi
00682
00683         The main difference with the old fortran version lies in
00684         the recursion that is used here. That cleans up the variables
00685         very much.
00686
00687         The contents of the AT.TMout array are:
00688         length,type,gamma5,gamma's
00689
00690         The space for the vectors in t is at most 14 * number.
00691
00692         The condition params[5] == 0 corresponds to finding gamma6*gamma7
00693         during the pick up of the matrices.

00831
00832         The recursive breakdown of a trace in 4 dimensions.
00833         We test first whether the trace has zero or two gamma's left.
00834         This case can be done quickly.
00835         Next we test whether we can eliminate adjacent objects that are
00836         the same.
00837         Then we test for Chisholm identities (I). First for identities
00838         with an odd number of gamma matrices (II), then for those with an
00839         even number of matrices (III). The special thing here is the demand
00840         that the contraction be between indices with 4 dimensions only.
00841         Then there is a scan for objects that are the same, not regarding
00842         their type (IV). This is exactly the same as in n dimensions.
00843         Finally we have a string left in which all objects are different (V).
00844         This case is treated by the routine Trace4no (no stands for no
00845         objects are the same).
00846
00847         In case I we have one d_ of which the result of the contraction
00848         has not yet been fixed.
00849         Case II gives just a reordering of the matrices and a factor -2.
00850         Case III gives two terms: one for the anti commutation, such that
00851         the number of intermediate matrices becomes odd and the other
00852         from the Chisholm rule for an odd number of matrices. Both have
00853         a factor 2.
00854         Case IV gives m+1 terms when m is the number of matrices inbetween.
00855         We take the shortest path. The sign alternates and all terms have
00856         a factor two, except for the last one.

4.95.1 Detailed Description

experimental routines for the optimization of FORTRAN or C output.

Definition in file optimize.cc.

4.95.2 Function Documentation

4.95.2.1 print_instr()

```
void print_instr (
            const vector< WORD > & instr,
            WORD num )
```

Definition at line 179 of file optimize.cc.

4.95.2.2 my_random_shuffle()

```
template<class RandomAccessIterator >
void my_random_shuffle (
            PHEAD RandomAccessIterator fr,
            RandomAccessIterator to )
```

Random shuffle

4.95.3 Description

Randomly permutes elements in the range [fr,to). Functionality is the same as C++'s "random_shuffle", but it uses Form's "wranf".

Definition at line 201 of file optimize.cc.

Referenced by find_Horner_MCTS().

4.95.3.1 get_expression()

```
LONG get_expression (
            int exprnr )
```

Get expression

4.95.4 Description

Reads an expression from the input file into a buffer (called optimize_expr). This buffer is used during the optimization process. Non-symbols are removed by ConvertToPoly and are put in temporary symbols.

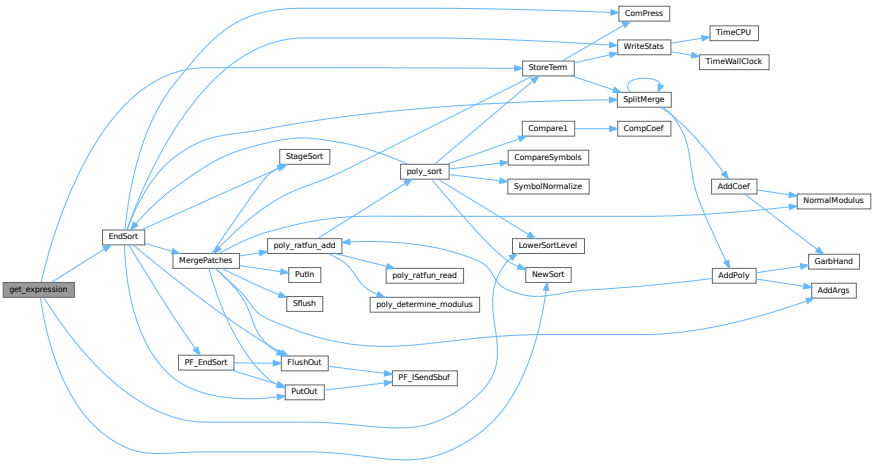
The return value is the length of the expression in WORDs, or a negative number if it failed.

Definition at line 225 of file optimize.cc.

References EndSort(), LowerSortLevel(), NewSort(), and StoreTerm().

Referenced by Optimize().

Here is the call graph for this function:



4.95.4.1 get_brackets()

```
vector< vector< WORD > > get_brackets ( )
```

Get brackets

4.95.5 Description

Checks whether the input expression (stored in optimize_expr) contains brackets. If so, this method replaces terms outside brackets by powers of SEPERATESYMBOL (equal brackets have equal powers) and the brackets are returned. If not, the result is empty.

Brackets are used for simultaneous optimization. The symbol SEPARATESYMBOL is always the first one used in a Horner scheme.

Definition at line 302 of file optimize.cc.

Referenced by Optimize().

4.95.5.1 count_operators() [1/2]

```
int count_operators (
            const WORD * expr,
            bool print = false )
```

Count operators

4.95.6 Description

Counts the number of operators in a Form-style expression.

Definition at line 422 of file optimize.cc.

Referenced by find_Horner_MCTS(), generate_instructions(), Optimize(), optimize_expression_given_Horner(), and optimize_greedy().

4.95.6.1 count_operators() [2/2]

```
int count_operators (
            const vector< WORD > & instr,
            bool print = false )
```

Count operators

4.95.7 Description

Counts the number of operators in a vector of instructions

Definition at line 476 of file optimize.cc.

4.95.7.1 occurrence_order()

```
vector< WORD > occurrence_order (
            const WORD * expr,
            bool rev )
```

Occurrence order

4.95.8 Description

Extracts all variables from an expression and sorts them with most occurring first (or last, with rev=true)

Definition at line 519 of file optimize.cc.

Referenced by Optimize().

4.95.8.1 getpower()

```
WORD getpower (
             const WORD * term,
             int var,
             int pos )
```

Horner tree building

4.95.9 Description

Given a Form-style expression (in a buffer in memory), this builds an expression tree. The tree is determined by a multivariate Horner scheme, i.e., something of the form:

1+y+x∗(2+y∗(1+y)+x∗(3-y∗(...)))

The order of the variables is given to the method "Horner_tree", which renumbers ad reorders the terms of the expression. Next, the recursive method "build_Horner_tree" does the actual tree construction.

The tree is represented in postfix notation. Tokens are of the following forms:

- SNUMBER tokenlength num den coefflength
- SYMBOL tokenlength variable power
- OPER_ADD or OPER_MUL

4.95.10 Note

Sets AN.poly_num_vars and allocates AN.poly_vars. The latter should be freed later. Get power of variable (helper function for build_Horner_tree)

4.95.11 Description

Returns the power of the variable "var", which is at position "pos" in this term, if it is present.

Definition at line 600 of file optimize.cc.

Referenced by build_Horner_tree().

4.95.11.1 fixarg()

```
void fixarg (
             UWORD * t,
             WORD & n )
```

Call GcdLong/DivLong with leading zeroes

4.95.12 Description

These method remove leading zeroes, so that GcdLong and DivLong can safely be called.

Definition at line 614 of file optimize.cc.

4.95.12.1 GcdLong_fix_args()

```
void GcdLong_fix_args (
             PHEAD UWORD * a,
             WORD na,
             UWORD * b,
             WORD nb,
             UWORD * c,
             WORD * nc )
```

Definition at line 620 of file optimize.cc.

4.95.12.2 DivLong_fix_args()

```
void DivLong_fix_args (
             UWORD * a,
             WORD na,
             UWORD * b,
             WORD nb,
             UWORD * c,
             WORD * nc,
             UWORD * d,
             WORD * nd )
```

Definition at line 626 of file optimize.cc.

4.95.12.3 build_Horner_tree()

```
void build_Horner_tree (
             const WORD ** terms,
             int numterms,
             int var,
             int maxvar,
             int pos,
             vector< WORD > * res )
```

Build the Horner tree

4.95.13 Description

Constructs the Horner tree. The method processes one variable and continues recursively until the Horner scheme is completed.

"terms" is a pointer to the starts of the terms. "numterms" is the number of terms to be processed. "var" is the next variable to be processed (index between 0 and #maxvar) and "maxvar" is the last variable to be processed, so that partial Horner trees can also be constructed. "pos" is the position that the power of "var" should be in (one level further in the recursion, "pos" has increased by 0 or 1 depending on whether the previous power was 0 or not). The result is written at the pointer "res".

This method also factors out gcds of the coefficients. The result should end with "gcd OPER_MUL" at all times, so that one level higher gcds can be extracted again.

```
bool term_compare (
            const WORD * a,
            const WORD * b )
```

Term compare (helper function for Horner_tree)

4.95.14 Description

Compares two terms of the form "L SYM 4 x n coeff" or "L coeff". Lower powers of lower-indexed symbols come first. This is used to sort the terms in correct order.

Definition at line 852 of file optimize.cc.

Referenced by Horner_tree().

4.95.14.1 Horner_tree()

```
vector< WORD > Horner_tree (
            const WORD * expr,
            const vector< WORD > & order )
```

Prepare Horner tree building

4.95.15 Description

This method renumbers the variables to 0...#vars-1 according to the specified order. Next, it stored pointer to individual terms and sorts the terms with higher power first. Then the sorted lists of power is used for the construction of the Horner tree.

Definition at line 873 of file optimize.cc.

4.95.15.3 generate_instructions()

```
vector< WORD > generate_instructions (
            const vector< WORD > & tree,
            bool do_CSE )
```

Generate instructions

4.95.16 Description

Converts the expression tree to a list of instructions that directly translate to code. Instructions are of the form:

expr.nr operator length [operands]+ trailing.zero

The operands are of the form:

length [(EXTRA)SYMBOL length variable power] coeff

This method only generates binary operators. Merging is done later. The method also checks for common subexpressions and eliminates them and the flag "do_CSE" is set.

4.95.17 Implementation details

The map "ID" keeps track of which subexpressions already exist. The key is formatted as one of the following:

SYMBOL x n SNUMBER coeff OPERATOR LHS RHS

with LHS/RHS formatted as one of the following:

SNUMBER idx 0 (EXTRA)SYMBOL x n

ID[symbol] or ID[operator] equals a subexpression number. ID[coeff] equals the position of the number in the input.

The stack s is used the process the postfix expression tree. Three-word tokens of the form:

SNUMBER idx.of.coeff 0 SYMBOL x n EXTRASYMBOL x 1

are pushed onto it. Operators pop two operands and push the resulting expression.

(Extra)symbols are 1-indexed, because -X is also needed to represent -1 times this term.

There is currently a bug. The notation cannot tell if there is a single bracket and then ignores the bracket.

TODO: check if this method performs properly if do_CSE=false

4.95.18.1 merge_operators()

```
vector< WORD > merge_operators (
            const vector< WORD > & all_instr,
            bool move_coeff )
```

Merge operators

4.95.19 Description

The input instructions form a binary DAG. This method merges expressions like

Z1 = a+b; Z2 = Z1+c;

into

Z2 = a+b+c;

An instruction is merged iff it only has one parent and the operator equals its parent's operator.

This still leaves some freedom: where should the coefficients end up in cases as:

Z1 = Z2 + x <=> Z1 = 2∗Z2 + x Z2 = 2∗x∗y Z2 = x∗y

Both are relevant, e.g. for CSE of the form "2∗x" and "2∗Z2". The flag "move_coeff" moves coefficients from LHS-like expressions to RHS-like expressions.

Furthermore, this method removes empty equation (Z1=0), that are introduced by some "optimize_greedy" substitutions.

4.95.20 Implementation details

Expressions are mostly traversed via a stack, so that parents are evaluated before their children.

With "move_coeff" set coefficients are moved, but this leads to some tricky cases, e.g.

Z1 = Z2 + x Z2 = 2∗y

Here Z2 reduces to the trivial equation Z2=y, which should be eliminated. Here the array skip[i] comes in.

Furthermore in the case

Z1 = Z2 + x Z2 = 2∗Z3 Z3 = x∗Z4 Z4 = y∗z

after substituting Z1 = 2∗Z3 + x, the parent expression for Z4 becomes Z3 instead of Z2. This is where renum_par[i] comes in.

Finally, once a coefficient has been moved, skip_coeff[i] is set and this coefficient is copied into the new expression anymore.

Definition at line 2402 of file optimize.cc.

4.95.20.1 find_optimizations()

```
vector< optimization > find_optimizations (
            const vector< WORD > & instr )
```

Find optimizations

4.95.21 Description

This method find all optimization of the form described in "class Optimization". It process every equation, looking for possible optimizations and stores them in a fast-access data structure to count the total improvement of an optimization.

Definition at line 2697 of file optimize.cc.

Referenced by optimize_greedy().

4.95.21.1 do_optimization()

```
bool do_optimization (
            const optimization optim,
            vector< WORD > & instr,
            int newid )
```

Do optimization

4.95.22 Description

This method performs an optimization. It scans through the equations of "optim.eqnidxs" and looks in which this optimization can still be performed (due to other performed optimizations this isn't always the case). If possible, it substitutes the common subexpression by a new extra symbol numbered "newid". Finally, the new extrasymbol is defined accordingly.

Substitutions may lead to trivial equations of the form "Zi=Zj", but these are removed in the end of the method. The method returns whether the substitution has been done once or more (or not).

Definition at line 2930 of file optimize.cc.

Referenced by optimize_greedy().

4.95.22.1 partial_factorize()

```
int partial_factorize (
            vector< WORD > & instr,
            int n,
            int improve )
```

Partial factorization of instructions

4.95.23 Description

This method performs partial factorization of instructions. In particular the following instructions

Z1 = x∗a∗b Z2 = x∗c∗d∗e Z3 = 2∗x + Z1 + Z2 + more

are replaced by

Z1 = a∗b Z2 = c∗d∗e Z3 = Zj + more Zi = 2 + Z1 + Z2 Zj = x∗Zi

Here it is necessary that no other equations refer to Z1 and Z2. The generation of trivial instructions (Zi=Zj or Zi=x) is prevented.

Definition at line 3479 of file optimize.cc.

Referenced by optimize_greedy().

4.95.23.1 optimize_greedy()

```
vector< WORD > optimize_greedy (
            vector< WORD > instr,
            LONG time_limit )
```

Optimize instructions greedily

4.95.24 Description

This method optimizes an expression greedily. It calls "find_optimizations" to obtain candidates and performs the best one(s) by calling "do_optimization".

How many different optimization are done, before "find_optimization" is called again, is determined by the settings "greedyminnum" and "greedymaxperc".

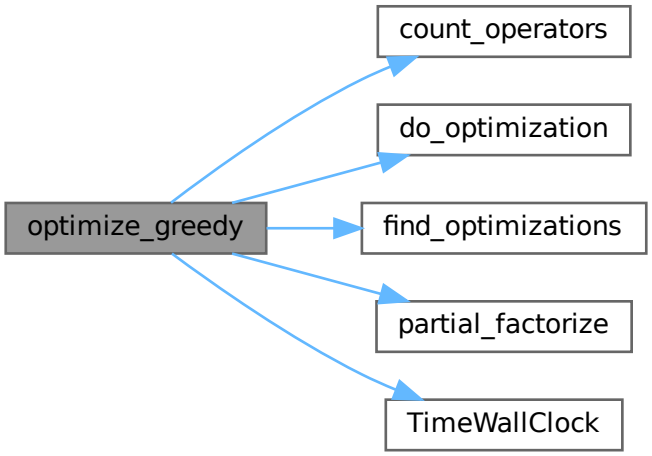
During the optimization process, sequences of zeroes are introduced in the instructions, since moving all instructions when one gets optimized, is very costly. Therefore, in the end, the instructions are "compressed" again to remove these extra zeroes.

Definition at line 3773 of file optimize.cc.

References count_operators(), do_optimization(), find_optimizations(), partial_factorize(), and TimeWallClock().

Referenced by optimize_expression_given_Horner().

Here is the call graph for this function:



4.95.24.1 recycle_variables()

```
vector< WORD > recycle_variables (
            const vector< WORD > & all_instr )
```

Recycle variables

4.95.25 Description

The current input uses many temporary variables. Many of them become obsolete at some point during the evaluation of the code, so can be recycled. This method renumbers the temporary variables, so that they are recycled. Furthermore, the input is order in depth-first order, so that the instructions can be performed consecutively.

4.95.26 Implementation details

First, for each subDAG, an estimate for the number of variables needed is made. This is done by the following recursive formula:

#vars(x) = max(#vars(ch_i(x)) + i),

with ch_i(x) the i-th child of x, where the childs are ordered w.r.t. #vars(ch_i). This formula is exact if the input forms a tree, and otherwise gives a reasonable estimate.

Then, the instructions are reordered in a depth-first order with childs ordered w.r.t. #vars. Next, the times that variables become obsolete are found. Each LHS of an instruction is renumbered to the lowest-numbered temporary variable that is available at that time.

4.95.26.1 optimize_expression_given_Horner()

```
void optimize_expression_given_Horner ( )
```

Optimize expression given a Horner scheme

4.95.27 Description

This method picks one Horner scheme from the list of best Horner schemes, applies this scheme to the expression and then, depending on optimize.settings, does a common subexpression elimination (CSE) or performs greedy optimizations.

CSE is fast, while greedy might be slow. CSE followed by greedy is faster than greedy alone, but typically results in slightly worse code (not proven; just observed). eventually do greedy optimizations

Definition at line 4060 of file optimize.cc.

```
int Optimize (
            WORD exprnr,
            int do_print )
```

Optimization of expression

4.95.31 Description

This method takes an input expression and generates optimized code to calculate its value. The following methods are called to do so:

(1) get_expression : to read to expression

(2) get_brackets : find brackets for simultaneous optimization

(3) occurrence_order or find_Horner_MCTS : to determine (the) Horner scheme(s) to use; this depends on AO.↩ optimize.horner

(4) optimize_expression_given_Horner : to do the optimizations for each Horner scheme; this method does either CSE or greedy optimizations dependings on AO.optimize.method

(5) generate_output : to format the output in Form notation and store it in a buffer

(6a) optimize_print_code : to print the expression (for "Print") or (6b) generate_expression : to modify the expression (for "#Optimize")

On ParFORM, all the processes must call this function at the same time. Then

(1) Because only the master can access to the expression to be optimized, the master broadcast the expression to all the slaves after reading the expression (PF_get_expression).

(2) get_brackets reads optimize_expr as the input and it works also on the slaves. We leave it although the bracket information is not needed on the slaves (used in (5) on the master).

(3) and (4) find_Horner_MCTS and optimize_expression_given_Horner are parallelized.

(5), (6a) and (6b) are needed only on the master.

```
int ClearOptimize (
            void  )
```

Optimization of expression

4.95.32 Description

Clears the buffers that were used for optimization output. Clears the expression from the buffers (marks it to be dropped). Note: we need to use the expression by its name, because numbers may change if we drop other expressions between when we do the optimizations and clear the results (in execute.c). Also this is not 100% safe, because we could overwrite the optimized expression. But that can be done only in a Local or Global statement and hence we only have to test there that we might have to call ClearOptimize first. (in file comexpr.c)

4.97.1 Detailed Description

Message passing library independent functions of parform

This file contains functions needed for the parallel version of form3 these functions need no real link to the message passing libraries, they only need some interface dependent preprocessor definitions (check parallel.h). So there still need two different objectfiles to be compiled for mpi and pvm!

Definition in file parallel.c.

4.97.2 Macro Definition Documentation

4.97.2.1 PRINTFBUF

```
#define PRINTFBUF(
                TEXT,
                TERM,
                SIZE ) {}
```

Definition at line 124 of file parallel.c.

4.97.2.2 SWAP

```
#define SWAP(
              x,
              y )
```

Value:

```
    do { \
        char swap_tmp__[sizeof(x) == sizeof(y) ? (int)sizeof(x) : -1]; \
        memcpy(swap_tmp__, &y, sizeof(x)); \
        memcpy(&y, &x, sizeof(x)); \
        memcpy(&x, swap_tmp__, sizeof(x)); \
    } while (0)
```

Swaps the variables *x* and *y*. If sizeof(x) != sizeof(y) then a compilation error will occur. A set of memcpy calls with constant sizes is expected to be inlined by the optimisation.

Definition at line 131 of file parallel.c.

4.97.2.3 PACK_LONG

```
#define PACK_LONG(
              p,
              n )
```

Value:

```
    do { \
        *(p)++ = (UWORD)((ULONG)(n) & (ULONG)WORDMASK); \
        *(p)++ = (UWORD)(((ULONG)(n) » BITSINWORD) & (ULONG)WORDMASK); \
    } while (0)
```

Packs a LONG value *n* to a WORD buffer *p*.

Definition at line 142 of file parallel.c.

4.97.2.4 UNPACK_LONG

```
#define UNPACK_LONG(
              p,
              n )
```

Value:

```
    do { \
        (n) = (LONG)((((ULONG)(p)[1] & (ULONG)WORDMASK) « BITSINWORD) | ((ULONG)(p)[0] & (ULONG)WORDMASK));
      \
        (p) += 2; \
    } while (0)
```

Unpacks a LONG value *n* from a WORD buffer *p*.

Definition at line 151 of file parallel.c.

4.97.2.5 CHECK

```
#define CHECK(
              condition ) _CHECK(condition, __FILE__, __LINE__)
```

A simple check for unrecoverable errors.

Definition at line 160 of file parallel.c.

4.97.2.6 _CHECK

```
#define _CHECK(
               condition,
               file,
               line ) __CHECK(condition, file, line)
```

Definition at line 161 of file parallel.c.

4.97.2.7 __CHECK

```
#define __CHECK(
               condition,
               file,
               line )
```

Value:

```
    do { \
        if ( !(condition) ) { \
            Error0("Fatal error at " file ":" #line); \
            Terminate(-1); \
        } \
    } while (0)
```

Definition at line 162 of file parallel.c.

4.97.2.8 DBGOUT

```
#define DBGOUT(
               lv1,
               lv2,
               a ) do { if ( lv1 >= lv2 ) { printf a; fflush(stdout); } } while (0)
```

Definition at line 173 of file parallel.c.

4.97.2.9 DBGOUT_NINTERMS

```
#define DBGOUT_NINTERMS(
               lv,
               a )
```

Definition at line 176 of file parallel.c.

4.97.2.10 PF_STATS_SIZE

```
#define PF_STATS_SIZE 5
```

Definition at line 185 of file parallel.c.

4.97.2.11 PF_SNDFILEBUFSIZE

```
#define PF_SNDFILEBUFSIZE 4096
```

Definition at line 4225 of file parallel.c.

4.97.2.12 recvBuffer

```
#define recvBuffer logBuffer /* (master) The buffer for receiving messages.  */
```

Definition at line 4333 of file parallel.c.

4.97.3 Typedef Documentation

4.97.3.1 NODE

```
typedef struct NoDe NODE
```

A node for the tree of losers in the final sorting on the master.

4.97.4 Function Documentation

4.97.4.1 PF_RealTime()

```
LONG PF_RealTime (
            int i )
```

Returns the realtime in 1/100 sec. as a LONG.

Parameters

i	the timer will be reset if i == 0.

Returns

the real elapsed time in 1/100 second.

Definition at line 106 of file mpi.c.

Referenced by PF_Init().

4.97.4.2 PF_LibInit()

```
int PF_LibInit (
            int * argcp,
            char *** argvp )
```

Performs all library dependent initializations.

Parameters

argcp	pointer to the number of arguments.
argvp	pointer to the arguments.

Returns

0 if OK, nonzero on error.

Definition at line 128 of file mpi.c.

Referenced by PF_Init().

4.97.4.3 PF_LibTerminate()

```
int PF_LibTerminate (
            int error )
```

Exits mpi, when there is an error either indicated or happening, returnvalue is 1, else returnvalue is 0.

Parameters

error	an error code.

Returns

0 if OK, nonzero on error.

Definition at line 214 of file mpi.c.

Referenced by PF_Terminate().

4.97.4.4 PF_Probe()

```
int PF_Probe (
            int * src )
```

Probes the next incoming message. If src == PF_ANY_SOURCE this operation is blocking, otherwise nonblocking.

Parameters

in,out	*src*	the source process number. In output, the process number of actual found source.

Returns

the tag value of the next incoming message if found, 0 if a nonblocking probe (input src != PF_ANY_SOURCE) did not find any messages. A negative returned value indicates an error.

Definition at line 235 of file mpi.c.

4.97.4.5 PF_RecvWbuf()

```
int PF_RecvWbuf (
            WORD * b,
            LONG * s,
            int * src )
```

Blocking receive of a WORD buffer.

Parameters

out	*b*	the buffer to store the received data.
in,out	*s*	the size of the buffer. The output value is the actual size of the received data.
in,out	*src*	the source process number. The output value is the process number of actual source.

Returns

the received message tag. A negative value indicates an error.

Definition at line 342 of file mpi.c.

References PF_ReceiveRuntimeError().

Here is the call graph for this function:

4.97.4.6 PF_IRecvRbuf()

```
int PF_IRecvRbuf (
            PF_BUFFER * r,
            int bn,
            int from )
```

Posts nonblocking receive for the active receive buffer. The buffer is filled from full to stop.

Parameters

r	the PF_BUFFER struct for the nonblocking receive.
bn	the index of the cyclic buffer.
from	the source process number.

Returns

0 if OK, nonzero on error.

Definition at line 378 of file mpi.c.

4.97.4.7 PF_WaitRbuf()

```
int PF_WaitRbuf (
            PF_BUFFER * r,
            int bn,
            LONG * size )
```

Waits for the buffer *bn* to finish a pending nonblocking receive. It returns the received tag and in `*size` the number of field received. If the receive is already finished, just return the flag and size, else wait for it to finish, but also check for other pending receives.

Parameters

	r	the PF_BUFFER struct for the pending nonblocking receive.
	bn	the index of the cyclic buffer.
out	*size*	the actual size of received data.

Returns

the received message tag. A negative value indicates an error.

Definition at line 412 of file mpi.c.

4.97.4.8 PF_RawSend()

```
int PF_RawSend (
            int dest,
            void * buf,
            LONG l,
            int tag )
```

Sends *l* bytes from *buf* to *dest*. Returns 0 on success, or -1.

Parameters

dest	the destination process number.
buf	the send buffer.
l	the size of data in the send buffer in bytes.
tag	the message tag.

Returns

0 if OK, nonzero on error.

Definition at line 497 of file mpi.c.

Referenced by PF_MUnlock(), PF_ReceiveRuntimeError(), and PF_SendFile().

4.97.4.9 PF_RawRecv()

```
LONG PF_RawRecv (
            int * src,
            void * buf,
            LONG thesize,
            int * tag )
```

Receives not more than *thesize* bytes from *src*, returns the actual number of received bytes, or -1 on failure.

Parameters

in,out	*src*	the source process number. In output, that of the actual received message.
out	*buf*	the receive buffer.
	thesize	the size of the receive buffer in bytes.
out	*tag*	the message tag of the actual received message.

Returns

the actual sizeof received data in bytes, or -1 on failure.

Definition at line 518 of file mpi.c.

Referenced by PF_ReceiveRuntimeError(), and PF_RecvFile().

4.97.4.10 PF_RawProbe()

```
int PF_RawProbe (
            int * src,
            int * tag,
            int * bytesize )
```

Probes an incoming message.

Parameters

in,out	*src*	the source process number. In output, that of the actual received message.
in,out	*tag*	the message tag. In output, that of the actual received message.
out	*bytesize*	the size of incoming data in bytes.

Returns

0 if OK, nonzero on error.

Definition at line 542 of file mpi.c.

4.97.4.11 PF_RawIsend()

```
int PF_RawIsend (
            int dest,
            const void * buf,
            int count,
            MPI_Datatype type,
            int tag,
            MPI_Request * request )
```

Performs a nonblocking send.

Parameters

	dest	the destination process number.
in	*buf*	the send buffer.
	count	the number of elements in the send buffer.
	type	the datatype of the data in the send buffer.
	tag	the message tag.
out	*request*	the request handle for the nonblocking operation.

Returns

0 if OK, nonzero on error.

Definition at line 574 of file mpi.c.

4.97.4.12 PF_RawWaitAll()

```
int PF_RawWaitAll (
            int count,
            MPI_Request * request,
            MPI_Status * status )
```

Waits for all the given requests to complete.

Parameters

	count	the number of requests.
in,out	*request*	the array of request handles.
out	*status*	the array of status objects to store the status of each completed request.

Returns

0 if OK, nonzero on error.

Definition at line 594 of file mpi.c.

4.97.4.13 PF_Discard()

```
int PF_Discard (
            int * src,
            int * tag )
```

Discards an incoming message.

Parameters

in,out	*src*	the source process number. On output, that of the actual received message.
in,out	*tag*	the message tag. On output, that of the actual received message.

Returns

0 if OK, nonzero on error.

Definition at line 615 of file mpi.c.

4.97.4.14 PF_EndSort()

```
int PF_EndSort (
            void  )
```

Finishes a master sorting with collecting terms from slaves. Called by EndSort().

If this is not the masterprocess, just initialize the sendbuffers and return 0, else PF_EndSort() sends the rest of the terms in the sendbuffer to the next slave and a dummy message to all slaves with tag PF_ENDSORT_MSGTAG. Then it receives the sorted terms, sorts them using a recursive 'tree of losers' (PF_GetLoser()) and writes them to the outputfile.

Returns

1 if the sorting on the master was done. 0 if EndSort() still must perform a regular sorting because it is not at the ground level or not on the master or in the sequential mode or in the InParallel mode. -1 if an error occurred.

Remarks

The slaves will send the sorted terms back to the master in the regular sorting (after the initialization of the send buffer in PF_EndSort()). See PutOut() and FlushOut().

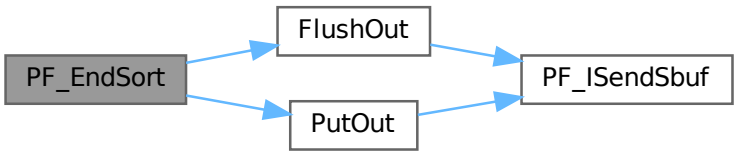
This function has been changed such that when it returns 1, AM.S0->TermsLeft is set correctly. But AM.S0->GenTerms is not set: it will be set after collecting the statistics from the slaves at the end of PF_Processor(). (TU 30 Jun 2011)

Definition at line 874 of file parallel.c.

References FlushOut(), and PutOut().

Referenced by EndSort().

Here is the call graph for this function:



4.97.4.15 PF_Deferred()

```
WORD PF_Deferred (
            WORD * term,
            WORD level )
```

Replaces Deferred() on the slaves.

Parameters

term	the term that must be multiplied by the contents of the current bracket.
level	the compiler level.

Returns

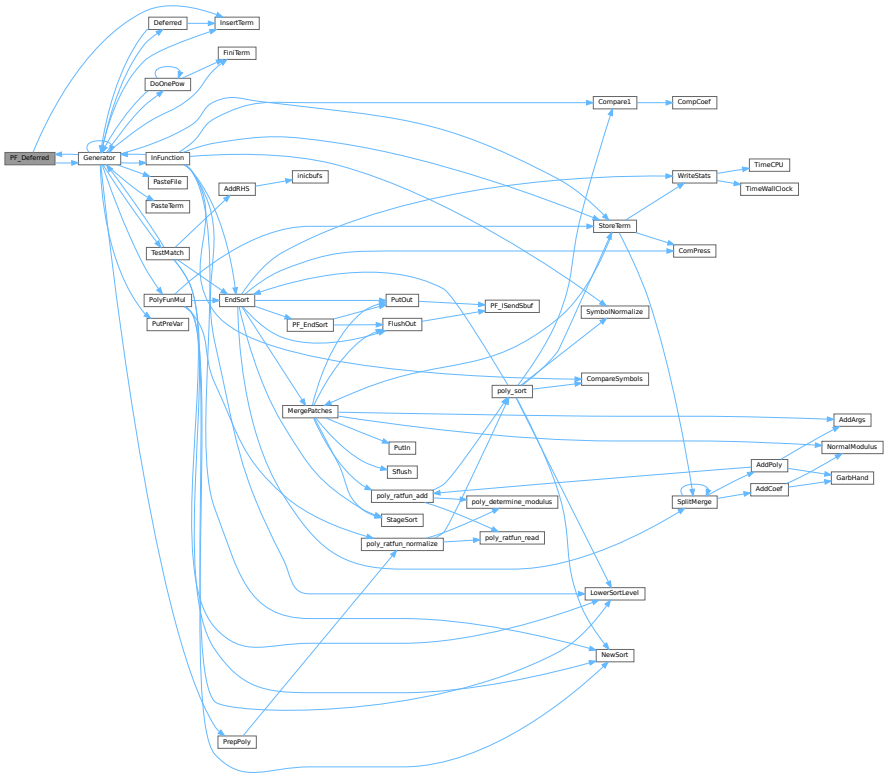
0 if OK, nonzero on error.

Definition at line 1201 of file parallel.c.

References Generator(), and InsertTerm().

Referenced by Generator().

Here is the call graph for this function:



4.97.4.16 PF_Processor()

```
int PF_Processor (
            EXPRESSIONS e,
            WORD i,
            WORD LastExpression )
```

Replaces parts of Processor() on the masters and slaves. On the master PF_Processor() is responsible for proper distribution of terms from the input file to the slaves. On the slaves it calls Generator() for all the terms that this process gets, but PF_GetTerm() gets terms from the master (not directly from infile).

Parameters

e	The pointer to the current expression.
i	The index for the current expression.
LastExpression	The flag indicating whether it is the last expression.

Returns

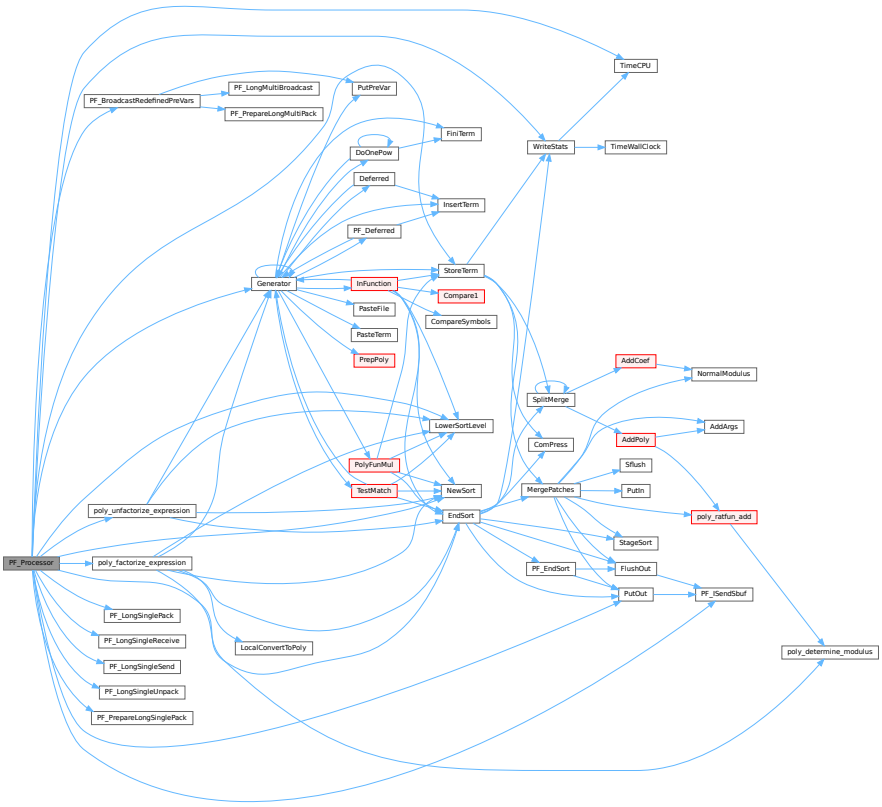
0 if OK, nonzero on error.

Definition at line 1533 of file parallel.c.

References EndSort(), Generator(), LowerSortLevel(), NewSort(), PACK_LONG, PF_BroadcastRedefinedPreVars(), PF_ISendSbuf(), PF_LongSinglePack(), PF_LongSingleReceive(), PF_LongSingleSend(), PF_LongSingleUnpack(), PF_PrepareLongSinglePack(), poly_factorize_expression(), poly_unfactorize_expression(), PutOut(), StoreTerm(), SWAP, TimeCPU(), and WriteStats().

Referenced by Processor().

Here is the call graph for this function:



4.97.4.17 PF_Init()

```
int PF_Init (
            int * argc,
            char *** argv )
```

All the library independent stuff. PF_LibInit() should do all library dependent initializations.

Parameters

argc	pointer to the number of arguments.
argv	pointer to the arguments.

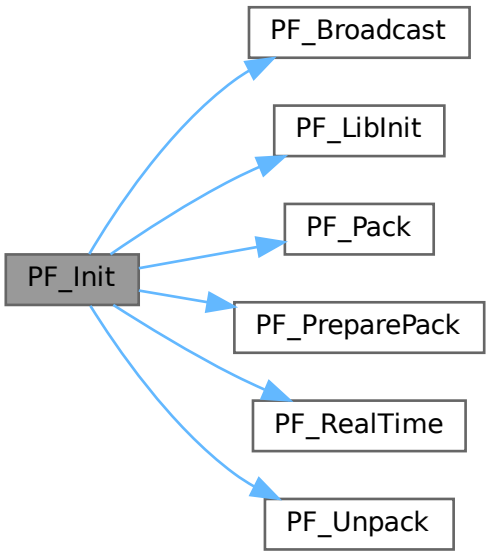
Returns

0 if OK, nonzero on error.

Definition at line 1947 of file parallel.c.

References PF_Broadcast(), PF_LibInit(), PF_Pack(), PF_PreparePack(), PF_RealTime(), and PF_Unpack().

Here is the call graph for this function:



4.97.4.18 PF_PreTerminate()

```
void PF_PreTerminate (
            int errorcode )
```

Prepares for termination. Called by Terminate().

Parameters

errorcode	an error code.

Definition at line 2041 of file parallel.c.

4.97.4.19 PF_Terminate()

```
int PF_Terminate (
            int errorcode )
```

Performs the finalization of ParFORM. To be called by Terminate().

Parameters

errorcode	an error code.

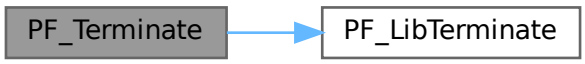
Returns

0 if OK, nonzero on error.

Definition at line 2061 of file parallel.c.

References PF_LibTerminate().

Here is the call graph for this function:



4.97.4.20 PF_GetSlaveTimes()

```
LONG PF_GetSlaveTimes (
            void  )
```

Returns the total CPU time of all slaves together. This function must be called on the master and all slaves.

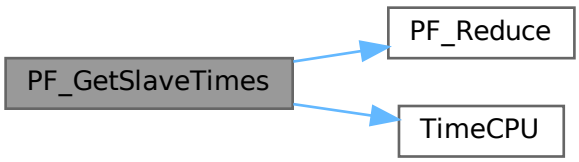
Returns

on the master, the sum of CPU times on all slaves.

Definition at line 2077 of file parallel.c.

References CHECK, PF_Reduce(), and TimeCPU().

Here is the call graph for this function:



4.97.4.21 PF_BroadcastNumber()

```
LONG PF_BroadcastNumber (
            LONG x )
```

Broadcasts a LONG value from the master to the all slaves.

Parameters

x	the number to be broadcast (set on the master).

Returns

the synchronised result.

Definition at line 2098 of file parallel.c.

References PF_Bcast().

Referenced by DoCheckpoint(), PF_BroadcastBuffer(), and StartVariables().

Here is the call graph for this function:

4.97.4.22 PF_BroadcastBuffer()

```
void PF_BroadcastBuffer (
            WORD ** buffer,
            LONG * length )
```

Broadcasts a buffer from the master to all the slaves.

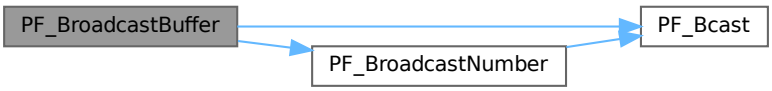
Parameters

in,out	*buffer*	on the master, the buffer to be broadcast. On the slaves, the buffer will be allocated if the length is greater than 0. The caller must free it.
in,out	*length*	on the master, the length of the buffer to be broadcast. On the slaves, it receives the length of transferred buffer. The actual transfer occurs only if the length is greater than 0.

Definition at line 2125 of file parallel.c.

References PF_Bcast(), and PF_BroadcastNumber().

Here is the call graph for this function:



4.97.4.23 PF_BroadcastString()

```
int PF_BroadcastString (
            UBYTE * str )
```

Broadcasts a string from the master to all slaves.

Parameters

in,out	*str*	The pointer to a null-terminated string.

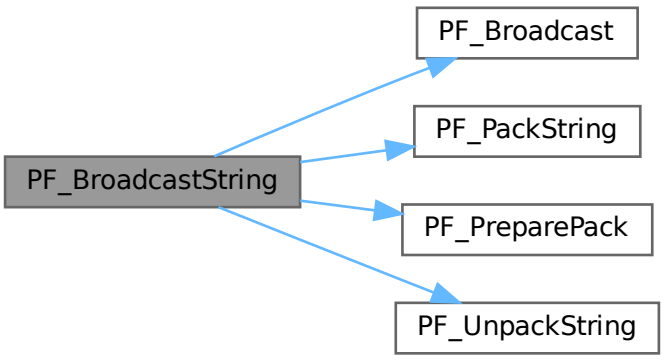
Returns

0 if OK, nonzero on error.

Definition at line 2167 of file parallel.c.

References PF_Broadcast(), PF_PackString(), PF_PreparePack(), and PF_UnpackString().

Here is the call graph for this function:



4.97.4.24 PF_BroadcastPreDollar()

```
int PF_BroadcastPreDollar (
            WORD ** dbuffer,
            LONG * newsize,
            int * numterms )
```

Broadcasts dollar variables set as a preprocessor variables. Only the master is able to make an assignment like #$a=g; where g is an expression: only the master has an access to the expression. So, the master broadcasts the result to slaves.

The result is in ∗dbuffer of the size is ∗newsize (in number of WORDs), +1 for trailing zero. For slave newsize and numterms are output parameters.

Parameters

in,out	*dbuffer*	the buffer for a dollar variable.
in,out	*newsize*	the size of the dollar variable in WORDs.
in,out	*numterms*	the number of terms in the dollar variable.

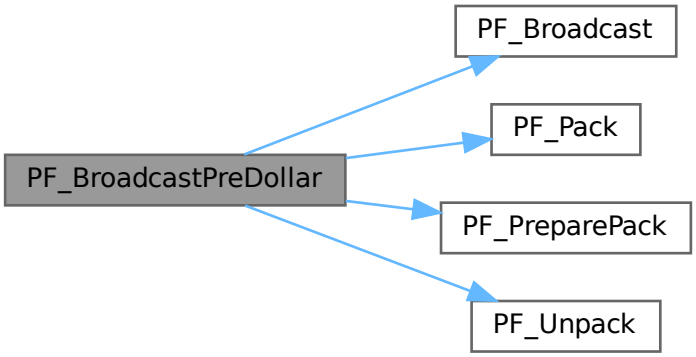
Returns

0 if OK, nonzero on error.

Definition at line 2222 of file parallel.c.

References PF_Broadcast(), PF_Pack(), PF_PreparePack(), and PF_Unpack().

Here is the call graph for this function:



4.97.4.25 PF_CollectModifiedDollars()

```
int PF_CollectModifiedDollars (
            void  )
```

Combines modified dollar variables on the all slaves, and store them into those on the master.

The potentially modified dollar variables are given in PotModdollars, and the number of them is given by NumPot↩ Moddollars.

The current module could be executed in parallel only if all potentially modified variables are listed in ModOptdollars, otherwise the module was switched to the sequential mode.

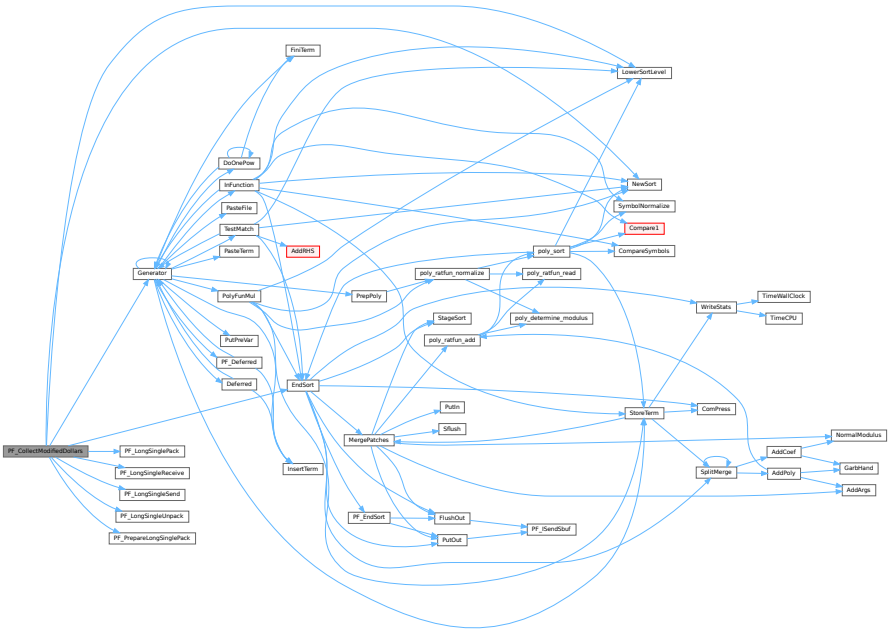
Returns

0 if OK, nonzero on error.

Definition at line 2509 of file parallel.c.

References EndSort(), Generator(), LowerSortLevel(), NewSort(), PF_LongSinglePack(), PF_LongSingleReceive(), PF_LongSingleSend(), PF_LongSingleUnpack(), PF_PrepareLongSinglePack(), VectorInit, VectorPtr, VectorReserve, and VectorSize.

Here is the call graph for this function:



4.97.4.26 PF_BroadcastModifiedDollars()

```
int PF_BroadcastModifiedDollars (
            void  )
```

Broadcasts modified dollar variables on the master to the all slaves.

The potentially modified dollar variables are given in PotModdollars, and the number of them is given by NumPot↩ Moddollars.

The current module could be executed in parallel only if all potentially modified variables are listed in ModOptdollars, otherwise the module was switched to the sequential mode. In either cases, we need to broadcast them.

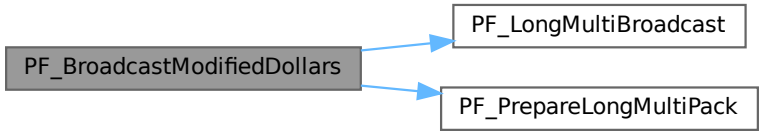
Returns

0 if OK, nonzero on error.

Definition at line 2788 of file parallel.c.

References PF_LongMultiBroadcast(), and PF_PrepareLongMultiPack().

Here is the call graph for this function:



4.97.4.27 PF_BroadcastRedefinedPreVars()

```
int PF_BroadcastRedefinedPreVars (
            void  )
```

Broadcasts preprocessor variables, which were changed by the Redefine statements in the current module, from the master to the all slaves.

The potentially redefined preprocessor variables are given in AC.pfirstnum, and the number of them is given by AC.numpfirstnum. For an actually redefined variable, the corresponding value in AC.inputnumbers is non-negative.

Returns

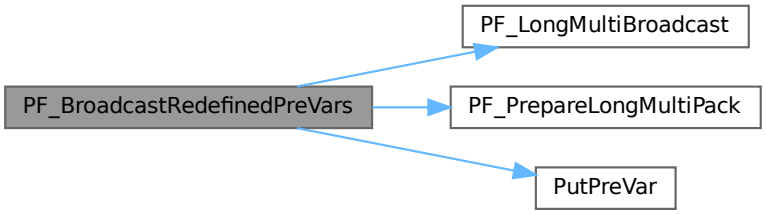
0 if OK, nonzero on error.

Definition at line 3005 of file parallel.c.

References PF_LongMultiBroadcast(), PF_PrepareLongMultiPack(), PutPreVar(), VectorPtr, and VectorReserve.

Referenced by PF_Processor().

Here is the call graph for this function:



4.97.4.28 PF_StoreInsideInfo()

```
int PF_StoreInsideInfo (
            void  )
```

Definition at line 3095 of file parallel.c.

4.97.4.29 PF_RestoreInsideInfo()

```
int PF_RestoreInsideInfo (
            void  )
```

Definition at line 3121 of file parallel.c.

4.97.4.30 PF_BroadcastCBuf()

```
int PF_BroadcastCBuf (
            int bufnum )
```

Broadcasts a compiler buffer specified by *bufnum* from the master to the all slaves.

Parameters

bufnum	The index of the compiler buffer to be broadcast.

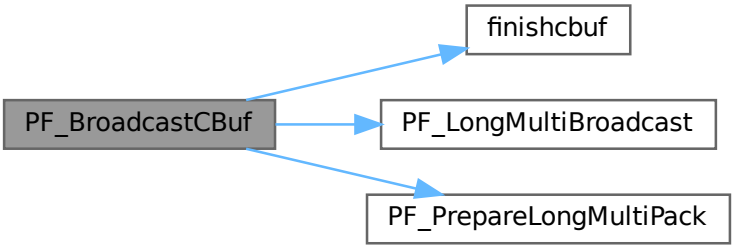
Returns

0 if OK, nonzero on error.

Definition at line 3147 of file parallel.c.

References CbUf::boomlijst, CbUf::Buffer, CbUf::BufferSize, CbUf::CanCommu, CbUf::dimension, finishcbuf(), CbUf::lhs, CbUf::numdum, CbUf::NumTerms, PF_LongMultiBroadcast(), PF_PrepareLongMultiPack(), CbUf::Pointer, CbUf::rhs, and CbUf::Top.

Here is the call graph for this function:



4.97.4.31 PF_BroadcastExpFlags()

```
int PF_BroadcastExpFlags (
            void  )
```

Broadcasts AR.expflags and several properties of each expression, e.g., e->vflags, from the master to all slaves.

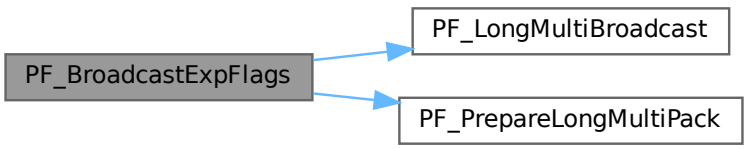
Returns

0 if OK, nonzero on error.

Definition at line 3258 of file parallel.c.

References PF_LongMultiBroadcast(), and PF_PrepareLongMultiPack().

Here is the call graph for this function:



4.97.4.32 PF_BroadcastExpr()

```
int PF_BroadcastExpr (
            EXPRESSIONS e,
            FILEHANDLE * file )
```

Broadcasts an expression from the master to the all slaves.

Parameters

e	The expression to be broadcast.
file	The file in which the expression is sitting.

Returns

0 if OK, nonzero on error.

Definition at line 3552 of file parallel.c.

Referenced by PF_BroadcastRHS().

4.97.4.33 PF_BroadcastRHS()

```
int PF_BroadcastRHS (
            void  )
```

Broadcasts expressions appearing in the right-hand side from the master to the all slaves.

Returns

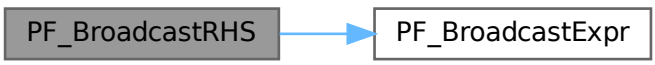
0 if OK, nonzero on error.

Definition at line 3580 of file parallel.c.

References PF_BroadcastExpr().

Referenced by Processor().

Here is the call graph for this function:



4.97.4.34 PF_InParallelProcessor()

```
int PF_InParallelProcessor (
            void  )
```

Processes expressions in the InParallel mode, i.e., dividing expressions marked by partodo over the slaves.

Returns

0 if OK, nonzero on error.

Definition at line 3627 of file parallel.c.

Referenced by Processor().

4.97.4.35 PF_SendFile()

```
int PF_SendFile (
            int to,
            FILE * fd )
```

Sends a file to the process specified by *to*.

Parameters

to	the destination process number.
fd	the file to be sent.

Returns

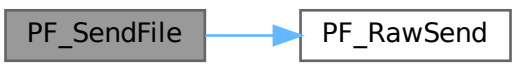
the size of sent data in bytes, or -1 on error.

Definition at line 4234 of file parallel.c.

References PF_RawSend().

Referenced by DoCheckpoint().

Here is the call graph for this function:



4.97.4.36 PF_RecvFile()

```
int PF_RecvFile (
            int from,
            FILE * fd )
```

Receives a file from the process specified by *from*.

Parameters

from	the source process number.
fd	the file to save the received data.

Returns

the size of received data in bytes, or -1 on error.

Definition at line 4272 of file parallel.c.

References PF_RawRecv().

Referenced by DoCheckpoint().

Here is the call graph for this function:

4.97.4.37 PF_MLock()

```
void PF_MLock (
            void  )
```

A function called by MLOCK(ErrorMessageLock) for slaves.

Definition at line 4353 of file parallel.c.

References VectorClear.

4.97.4.38 PF_MUnlock()

```
void PF_MUnlock (
             void  )
```

A function called by MUNLOCK(ErrorMessageLock) for slaves.

Definition at line 4369 of file parallel.c.

References PF_RawSend(), VectorEmpty, VectorPtr, and VectorSize.

Here is the call graph for this function:

4.97.4.39 PF_WriteFileToFile()

```
LONG PF_WriteFileToFile (
             int handle,
             UBYTE * buffer,
             LONG size )
```

Replaces WriteFileToFile() on the master and slaves.

It copies the given buffer into internal buffers if called between MLOCK(ErrorMessageLock) and MUNLOCK(Error↩ MessageLock) for slaves and handle is StdOut or LogHandle, otherwise calls WriteFileToFile().

Parameters

handle	a file handle that specifies the output.
buffer	a pointer to the source buffer containing the data to be written.
size	the size of data to be written in bytes.

Returns

the actual size of data written to the output in bytes.

Definition at line 4398 of file parallel.c.

References VectorClear, VectorPtr, VectorPushBacks, and VectorSize.

4.97.4.40 PF_FlushStdOutBuffer()

```
void PF_FlushStdOutBuffer (
            void  )
```

Explicitly Flushes the buffer for the standard output on the master, which is used if PF_ENABLE_STDOUT_↩ BUFFERING is defined.

Definition at line 4492 of file parallel.c.

References VectorClear, VectorPtr, and VectorSize.

4.97.4.41 PF_FreeErrorMessageBuffers()

```
void PF_FreeErrorMessageBuffers (
            void  )
```

Frees the buffers allocated for the synchronized output.

Currently, not used anywhere, but could be used in PF_Terminate().

Definition at line 4637 of file parallel.c.

References VectorFree.

4.97.4.42 PF_ReceiveRuntimeError()

```
void PF_ReceiveRuntimeError (
            void  )
```

Handles a runtime error message received from another process. It ultimately calls Terminate(-1).

Definition at line 4820 of file parallel.c.

References CHECK, PF_RawRecv(), and PF_RawSend().

Referenced by PF_RecvWbuf().

Here is the call graph for this function:

01861              * EndSort() overrides AR.outfile->PObuffer etc. (See also PF_EndSort()),
01862              * but it causes a problem because
01863              *  (1) PF_EndSort() sets AR.outfile->PObuffer to a send-buffer.
01864              *  (2) RevertScratch() clears AR.infile, but then swaps buffers of AR.infile
01865              *      and AR.outfile.
01866              *  (3) RHS expressions are stored to AR.infile->PObuffer.
01867              *  (4) Again, PF_EndSort() sets AR.outfile->PObuffer, but now AR.outfile->PObuffer
01868              *      == AR.infile->PObuffer because of (1) and (2).
01869              *  (5) The result goes to AR.outfile. This breaks the RHS expressions,
01870              *      which may be needed for the next expression.
01871              * Solution: backup & restore AR.outfile->PObuffer etc. (TU 14 Sep 2011)

04298 /*
04299  * If the master and slaves output statistics or error messages to the same stream
04300  * or file (e.g., the standard output or the log file) simultaneously, then
04301  * a mixing of their outputs can occur. To avoid this, TFORM uses a lock of
04302  * ErrorMessageLock, but there is no locking functionality in the original MPI
04303  * specification. We need to synchronise the output from the master and slaves.
04304  *
04305  * The idea of the synchronised output (by, e.g., MesPrint()) implemented here is
04306  *   Slaves:
04307  *     1. Save the output by WriteFile() (set to PF_WriteFileToFile())
04308  *        into some buffers between MLOCK(ErrorMessageLock) and
04309  *        MUNLOCK(ErrorMessageLock), which call PF_MLock() and PF_MUnlock(),
04310  *        respectively. The output for AM.StdOut and AC.LogHandle are saved to
04311  *        the buffers.
04312  *     2. At MUNLOCK(ErrorMessageLock), send the output in the buffer to the master,
04313  *        with PF_STDOUT_MSGTAG or PF_LOG_MSGTAG.
04314  *   Master:
04315  *     1. Receive the buffered output from slaves, and write them by
04316  *        WriteFileToFile().
04317  *   The main problem is how and where the master receives messages from
04318  *   the slaves (PF_ReceiveErrorMessage()). For this purpose there are three
04319  *   helper functions: PF_CatchErrorMessages() and PF_CatchErrorMessagesForAll()
04320  *   which remove messages with PF_STDOUT_MSGTAG or PF_LOG_MSGTAG from the top
04321  *   of the message queue, and PF_ProbeWithCatchingErrorMessages() which is same as
04322  *   PF_Probe() except removing these messages.
04323  */

04412      * On my computer, sometimes a single linefeed "\n" sent to the standard
04413      * output is ignored on the execution of mpiexec. A typical example is:
04414      *   $ cat foo.c
04415      *     #include <unistd.h>
04416      *     int main() {
04417      *       write(1, "    ", 4);
04418      *       write(1, "\n", 1);
04419      *       write(1, "    ", 4);
04420      *       write(1, "123\n", 4);
04421      *       return 0;
04422      *     }
04423      * or even as a shell script:
04424      *   $ cat foo.sh
04425      *     #! bin/sh
04426      *     printf "    "
04427      *     printf "\n"
04428      *     printf "    "
04429      *     printf "123\n"
04430      * When I ran it on mpiexec
04431      *   $ while :; do mpiexec -np 1 ./foo.sh; done
04432      * I observed the single linefeed (printf "\n") was sometimes ignored. Even
04433      * though this phenomenon might be specific to my environment, I added this
04434      * code because someone may encounter a similar phenomenon and feel it
04435      * frustrating. (TU 16 Jun 2011)
04436      *
04437      * Phenomenon:
04438      *   A single linefeed sent to the standard output occasionally ignored
04439      *   on mpiexec.
04440      *
04441      * Environment:
04442      *   openSUSE 11.4 (x86_64)
04443      *   kernel: 2.6.37.6-0.5-desktop
04444      *   gcc: 4.5.1 20101208
04445      *   mpich2-1.3.2p1 configured with '--enable-shared --with-pm=smpd'
04446      *
04447      * Solution:
04448      *   In Unix (in which Uwrite() calls write() system call without any buffering),
04449      *   we perform the line buffering here. A single linefeed is also buffered.
04450      *
04451      * XXX:
04452      *   At the end of the program the buffered output (text without LF) will not be flushed,
04453      *   i.e., will not be written to the standard output. This is not problematic at a normal run.
04454      *   The buffer can be explicitly flushed by PF_FlushStdOutBuffer().
04455      */

              count,
              type ) PF_LongMultiUnpackImpl(buffer, count, sizeof_datatype(type), type)
```

Definition at line 247 of file parallel.h.

4.99.3 Function Documentation

4.99.3.1 PF_ISendSbuf()

```
int PF_ISendSbuf (
             int to,
             int tag )  [extern]
```

Nonblocking send operation. It sends everything from `buff` to `fill` of the active buffer. Depending on *tag* it also can do waiting for other sends to finish or set the active buffer to the next one.

Parameters

to	the destination process number.
tag	the message tag.

Returns

0 if OK, nonzero on error.

Definition at line 266 of file mpi.c.

Referenced by FlushOut(), PF_Processor(), and PutOut().

4.99.3.2 PF_Bcast()

```
int PF_Bcast (
            void * buffer,
            int count )  [extern]
```

Broadcasts a message from the master to slaves.

Parameters

in,out	*buffer*	the starting address of buffer. The contents in this buffer on the master will be transferred to those on the slaves.
	count	the length of the buffer in bytes.

Returns

0 if OK, nonzero on error.

Definition at line 452 of file mpi.c.

Referenced by PF_BroadcastBuffer(), and PF_BroadcastNumber().

4.99.3.3 PF_Reduce()

```
int PF_Reduce (
            const void * sendbuf,
            void * recvbuf,
            int count,
            MPI_Datatype type,
            MPI_Op op,
            int root )  [extern]
```

Performs a reduce operation across all processes.

Parameters

in	*sendbuf*	the buffer containing the data to be reduced.
out	*recvbuf*	the buffer to store the reduced result (only for the root process).
	count	the number of elements in the buffers.
	type	the datatype of the elements.
	op	the operation to apply.
	root	the root process number.

Returns

0 if OK, nonzero on error.

Definition at line 475 of file mpi.c.

Referenced by PF_GetSlaveTimes().

4.99.3.4 PF_RawSend()

```
int PF_RawSend (
            int dest,
            void * buf,
            LONG l,
            int tag )  [extern]
```

Sends *l* bytes from *buf* to *dest*. Returns 0 on success, or -1.

Parameters

dest	the destination process number.
buf	the send buffer.
l	the size of data in the send buffer in bytes.
tag	the message tag.

Returns

0 if OK, nonzero on error.

Definition at line 497 of file mpi.c.

4.99.3.5 PF_RawRecv()

```
LONG PF_RawRecv (
            int * src,
            void * buf,
            LONG thesize,
            int * tag )  [extern]
```

Receives not more than *thesize* bytes from *src*, returns the actual number of received bytes, or -1 on failure.

Parameters

in,out	*src*	the source process number. In output, that of the actual received message.
out	*buf*	the receive buffer.
	thesize	the size of the receive buffer in bytes.
out	*tag*	the message tag of the actual received message.

Returns

the actual sizeof received data in bytes, or -1 on failure.

Definition at line 518 of file mpi.c.

4.99.3.6 PF_PreparePack()

```
int PF_PreparePack (
            void  )  [extern]
```

Prepares for the next pack operations on the sender.

Returns

0 if OK, nonzero on error.

Definition at line 736 of file mpi.c.

Referenced by Optimize(), PF_BroadcastPreDollar(), PF_BroadcastString(), and PF_Init().

4.99.3.7 PF_Pack()

```
int PF_Pack (
            const void * buffer,
            size_t count,
            MPI_Datatype type )  [extern]
```

Adds data into the pack buffer.

Parameters

buffer	the pointer to the buffer storing the data to be packed.
count	the number of elements in the buffer.
type	the data type of elements in the buffer.

Returns

0 if OK, nonzero on error.

Definition at line 754 of file mpi.c.

References MPI_ERRCODE_CHECK.

Referenced by Optimize(), PF_BroadcastPreDollar(), and PF_Init().

4.99.3.8 PF_Unpack()

```
int PF_Unpack (
            void * buffer,
            size_t count,
            MPI_Datatype type )  [extern]
```

Retrieves the next data in the pack buffer.

Parameters

out	*buffer*	the pointer to the buffer to store the unpacked data.
	count	the number of elements of data to be received.
	type	the data type of elements of data to be received.

Returns

0 if OK, nonzero on error.

Definition at line 783 of file mpi.c.

References MPI_ERRCODE_CHECK.

Referenced by Optimize(), PF_BroadcastPreDollar(), and PF_Init().

4.99.3.9 PF_PackString()

```
int PF_PackString (
            const UBYTE * str )  [extern]
```

Packs a string *str* into the packed buffer PF_packbuf, including the trailing zero.

The first element (PF_INT) is the length of the packed portion of the string. If the string does not fit to the buffer PF↩ _packbuf, the function packs only the initial portion. It returns the number of packed bytes, so if (str[length-1]=='\0') then the whole string fits to the buffer, if not, then the rest (str+length) must be packed and send again. On error, the function returns the negative error code.

One exception: the string "\0!\0" is used as an image of the NULL, so all 3 characters will be packed.

Parameters

str	a string to be packed.

Returns

the number of packed bytes, or a negative value on failure.

Definition at line 818 of file mpi.c.

Referenced by PF_BroadcastString().

4.99.3.10 PF_UnpackString()

```
int PF_UnpackString (
            UBYTE * str )  [extern]
```

Unpacks a string to *str* from the packed buffer PF_packbuf, including the trailing zero.

It returns the number of unpacked bytes, so if (str[length-1]=='\0') then the whole string was unpacked, if not, then the rest must be appended to (str+length). On error, the function returns the negative error code.

Parameters

out	*str*	the buffer to store the unpacked string

Returns

the number of unpacked bytes, or a negative value on failure.

Definition at line 886 of file mpi.c.

Referenced by PF_BroadcastString().

4.99.3.11 PF_Send()

```
int PF_Send (
              int to,
              int tag )  [extern]
```

Sends the contents in the pack buffer to the process specified by *to*.

Example:

```
if ( PF.me == SRC ) {
  PF_PreparePack();
  // Packing operations here...
  PF_Send(DEST, TAG);
}
else if ( PF.me == DEST ) {
  PF_Receive(SRC, TAG, &actual_src, &actual_tag);
  // Unpacking operations here...
}
```

Parameters

to	the destination process number.
tag	the message tag.

Returns

0 if OK, nonzero on error.

Definition at line 933 of file mpi.c.

References MPI_ERRCODE_CHECK.

4.99.3.12 PF_Receive()

```
int PF_Receive (
              int src,
              int tag,
              int * psrc,
              int * ptag )  [extern]
```

Receives data into the pack buffer from the process specified by *src*. This function allows &src == psrc or &tag == ptag. Either *psrc* or *ptag* can be NULL.

See the example of PF_Send().

Parameters

	src	the source process number (can be PF_ANY_SOURCE).
	tag	the source message tag (can be PF_ANY_TAG).
out	*psrc*	the actual source process number of received message.
out	*ptag*	the received message tag.

Returns

0 if OK, nonzero on error.

Definition at line 959 of file mpi.c.

References MPI_ERRCODE_CHECK.

4.99.3.13 PF_Broadcast()

```
int PF_Broadcast (
            void  )  [extern]
```

Broadcasts the contents in the pack buffer on the master to those on the slaves.

Example:

```
if ( PF.me == MASTER ) {
  PF_PreparePack();
  // Packing operations here...
}
PF_Broadcast();
if ( PF.me != MASTER ) {
  // Unpacking operations here...
}
```

Returns

0 if OK, nonzero on error.

Definition at line 994 of file mpi.c.

References MPI_ERRCODE_CHECK.

Referenced by Optimize(), PF_BroadcastPreDollar(), PF_BroadcastString(), and PF_Init().

4.99.3.14 PF_PrepareLongSinglePack()

```
int PF_PrepareLongSinglePack (
            void  )  [extern]
```

Prepares for the next long-single-pack operations on the sender.

Returns

0 if OK, nonzero on error.

Definition at line 1561 of file mpi.c.

Referenced by PF_CollectModifiedDollars(), and PF_Processor().

4.99.3.15 PF_LongSinglePack()

```
int PF_LongSinglePack (
            const void * buffer,
            size_t count,
            MPI_Datatype type )  [extern]
```

Adds data into the "long single" pack buffer.

Parameters

buffer	the pointer to the buffer storing the data to be packed.
count	the number of elements in the buffer.
type	the data type of elements in the buffer.

Returns

0 if OK, nonzero on error.

Definition at line 1579 of file mpi.c.

Referenced by PF_CollectModifiedDollars(), and PF_Processor().

4.99.3.16 PF_LongSingleUnpack()

```
int PF_LongSingleUnpack (
            void * buffer,
            size_t count,
            MPI_Datatype type )  [extern]
```

Retrieves the next data in the "long single" pack buffer.

Parameters

out	*buffer*	the pointer to the buffer to store the unpacked data.
	count	the number of elements of data to be received.
	type	the data type of elements of data to be received.

Returns

0 if OK, nonzero on error.

Definition at line 1613 of file mpi.c.

Referenced by PF_CollectModifiedDollars(), and PF_Processor().

4.99.3.17 PF_LongSingleSend()

```
int PF_LongSingleSend (
            int to,
            int tag )  [extern]
```

Sends the contents in the "long single" pack buffer to the process specified by *to*.

Example:

```
if ( PF.me == SRC ) {
  PF_PrepareLongSinglePack();
  // Packing operations here...
  PF_LongSingleSend(DEST, TAG);
}
else if ( PF.me == DEST ) {
  PF_LongSingleReceive(SRC, TAG, &actual_src, &actual_tag);
  // Unpacking operations here...
}
```

Parameters

to	the destination process number.
tag	the message tag.

Returns

0 if OK, nonzero on error.

Definition at line 1650 of file mpi.c.

Referenced by PF_CollectModifiedDollars(), and PF_Processor().

4.99.3.18 PF_LongSingleReceive()

```
int PF_LongSingleReceive (
            int src,
            int tag,
            int * psrc,
            int * ptag )  [extern]
```

Receives data into the "long single" pack buffer from the process specified by *src*. This function allows &src == psrc or &tag == ptag. Either *psrc* or *ptag* can be NULL.

See the example of PF_LongSingleSend().

Parameters

	src	the source process number (can be PF_ANY_SOURCE).
	tag	the source message tag (can be PF_ANY_TAG).
out	*psrc*	the actual source process number of received message.
out	*ptag*	the received message tag.

Returns

0 if OK, nonzero on error.

Definition at line 1693 of file mpi.c.

Referenced by PF_CollectModifiedDollars(), and PF_Processor().

4.99.3.19 PF_PrepareLongMultiPack()

```
int PF_PrepareLongMultiPack (
            void  )  [extern]
```

Prepares for the next long-multi-pack operations on the sender.

Returns

0 if OK, nonzero on error.

Definition at line 1752 of file mpi.c.

Referenced by Optimize(), PF_BroadcastCBuf(), PF_BroadcastExpFlags(), PF_BroadcastModifiedDollars(), and PF_BroadcastRedefinedPreVars().

4.99.3.20 PF_LongMultiPackImpl()

```
int PF_LongMultiPackImpl (
            const void * buffer,
            size_t count,
            size_t eSize,
            MPI_Datatype type )  [extern]
```

Adds data into the "long multi" pack buffer.

Parameters

buffer	the pointer to the buffer storing the data to be packed.
count	the number of elements in the buffer.
eSize	the byte size of each element of data.
type	the data type of elements in the buffer.

Returns

0 if OK, nonzero on error.

Definition at line 1771 of file mpi.c.

References PF_LongMultiPackImpl().

Referenced by PF_LongMultiPackImpl().

Here is the call graph for this function:

4.99.3.21 PF_LongMultiUnpackImpl()

```
int PF_LongMultiUnpackImpl (
            void * buffer,
            size_t count,
            size_t eSize,
            MPI_Datatype type )  [extern]
```

Retrieves the next data in the "long multi" pack buffer.

Parameters

out	*buffer*	the pointer to the buffer to store the unpacked data.
	count	the number of elements of data to be received.
	eSize	the byte size of each element of data.
	type	the data type of elements of data to be received.

Returns

0 if OK, nonzero on error.

Definition at line 1830 of file mpi.c.

References PF_LongMultiUnpackImpl().

Referenced by PF_LongMultiUnpackImpl().

Here is the call graph for this function:

4.99.3.22 PF_LongMultiBroadcast()

```
int PF_LongMultiBroadcast (
              void  )  [extern]
```

Broadcasts the contents in the "long multi" pack buffer on the master to those on the slaves.

Example:

```
if ( PF.me == MASTER ) {
  PF_PrepareLongMultiPack();
  // Packing operations here...
}
PF_LongMultiBroadcast();
if ( PF.me != MASTER ) {
  // Unpacking operations here...
}
```

Returns

0 if OK, nonzero on error.

Definition at line 1916 of file mpi.c.

Referenced by Optimize(), PF_BroadcastCBuf(), PF_BroadcastExpFlags(), PF_BroadcastModifiedDollars(), and PF_BroadcastRedefinedPreVars().

4.99.3.23 PF_EndSort()

```
int PF_EndSort (
            void  )  [extern]
```

Finishes a master sorting with collecting terms from slaves. Called by EndSort().

If this is not the masterprocess, just initialize the sendbuffers and return 0, else PF_EndSort() sends the rest of the terms in the sendbuffer to the next slave and a dummy message to all slaves with tag PF_ENDSORT_MSGTAG. Then it receives the sorted terms, sorts them using a recursive 'tree of losers' (PF_GetLoser()) and writes them to the outputfile.

Returns

1 if the sorting on the master was done. 0 if EndSort() still must perform a regular sorting because it is not at the ground level or not on the master or in the sequential mode or in the InParallel mode. -1 if an error occurred.

Remarks

The slaves will send the sorted terms back to the master in the regular sorting (after the initialization of the send buffer in PF_EndSort()). See PutOut() and FlushOut().

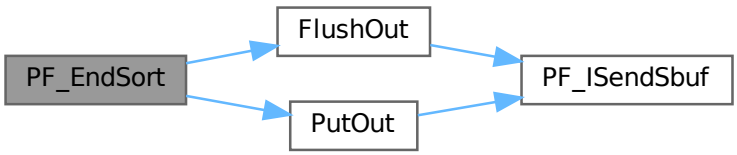
This function has been changed such that when it returns 1, AM.S0->TermsLeft is set correctly. But AM.S0->GenTerms is not set: it will be set after collecting the statistics from the slaves at the end of PF_Processor(). (TU 30 Jun 2011)

Definition at line 874 of file parallel.c.

References FlushOut(), and PutOut().

Referenced by EndSort().

Here is the call graph for this function:



4.99.3.24 PF_Deferred()

```
WORD PF_Deferred (
            WORD * term,
            WORD level )  [extern]
```

Replaces Deferred() on the slaves.

Parameters

term	the term that must be multiplied by the contents of the current bracket.
level	the compiler level.

Returns

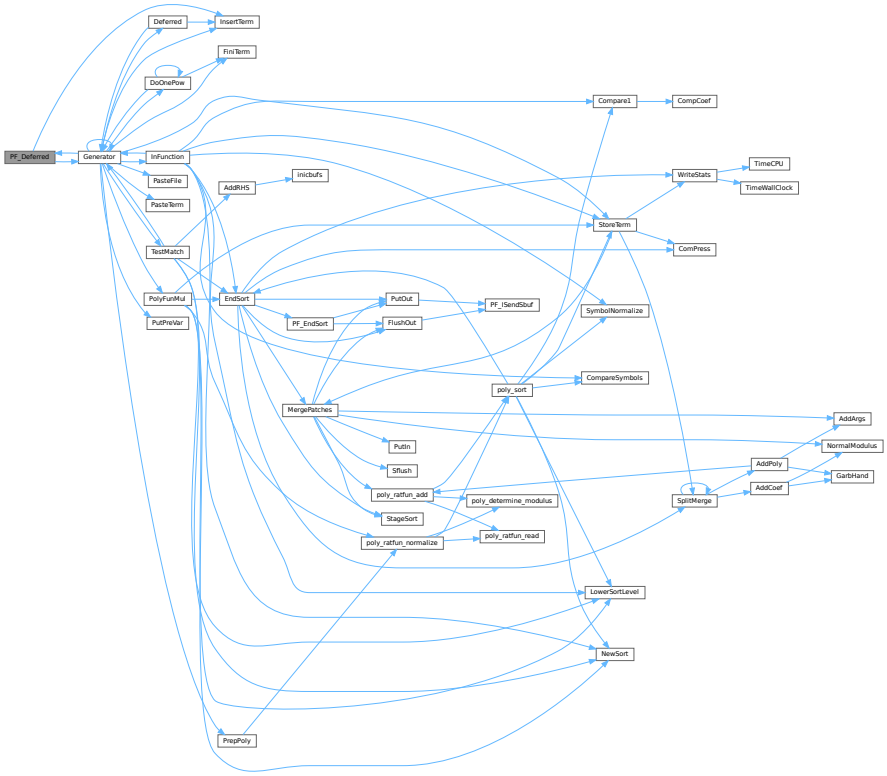
0 if OK, nonzero on error.

Definition at line 1201 of file parallel.c.

References Generator(), and InsertTerm().

Referenced by Generator().

Here is the call graph for this function:



4.99.3.25 PF_Processor()

```
int PF_Processor (
            EXPRESSIONS e,
            WORD i,
            WORD LastExpression )  [extern]
```

Replaces parts of Processor() on the masters and slaves. On the master PF_Processor() is responsible for proper distribution of terms from the input file to the slaves. On the slaves it calls Generator() for all the terms that this process gets, but PF_GetTerm() gets terms from the master (not directly from infile).

Parameters

e	The pointer to the current expression.
i	The index for the current expression.
LastExpression	The flag indicating whether it is the last expression.

Returns

0 if OK, nonzero on error.

Definition at line 1533 of file parallel.c.

References EndSort(), Generator(), LowerSortLevel(), NewSort(), PACK_LONG, PF_BroadcastRedefinedPreVars(), PF_ISendSbuf(), PF_LongSinglePack(), PF_LongSingleReceive(), PF_LongSingleSend(), PF_LongSingleUnpack(), PF_PrepareLongSinglePack(), poly_factorize_expression(), poly_unfactorize_expression(), PutOut(), StoreTerm(), SWAP, TimeCPU(), and WriteStats().

4.99.3.26 PF_Init()

```
int PF_Init (
            int * argc,
            char *** argv )  [extern]
```

All the library independent stuff. PF_LibInit() should do all library dependent initializations.

Parameters

argc	pointer to the number of arguments.
argv	pointer to the arguments.

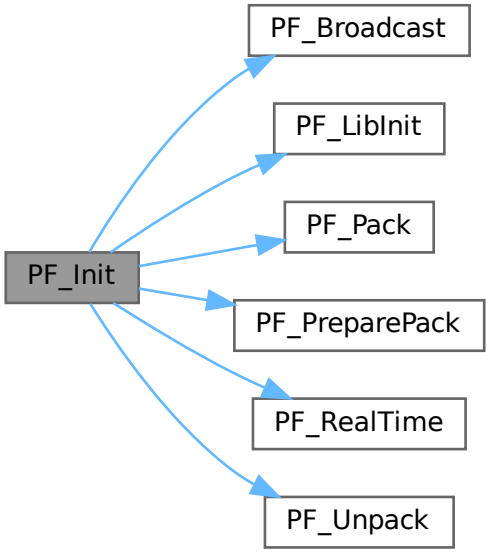
Returns

0 if OK, nonzero on error.

Definition at line 1947 of file parallel.c.

References PF_Broadcast(), PF_LibInit(), PF_Pack(), PF_PreparePack(), PF_RealTime(), and PF_Unpack().

Here is the call graph for this function:



4.99.3.27 PF_PreTerminate()

```
void PF_PreTerminate (
            int errorcode )  [extern]
```

Prepares for termination. Called by Terminate().

Parameters

errorcode	an error code.

Definition at line 2041 of file parallel.c.

4.99.3.28 PF_Terminate()

```
int PF_Terminate (
            int errorcode )  [extern]
```

Performs the finalization of ParFORM. To be called by Terminate().

Parameters

errorcode	an error code.

Returns

0 if OK, nonzero on error.

Definition at line 2061 of file parallel.c.

References PF_LibTerminate().

Here is the call graph for this function:

4.99.3.29 PF_GetSlaveTimes()

```
LONG PF_GetSlaveTimes (
            void  )  [extern]
```

Returns the total CPU time of all slaves together. This function must be called on the master and all slaves.

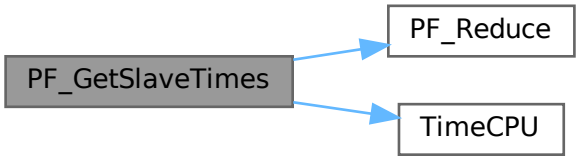
Returns

on the master, the sum of CPU times on all slaves.

Definition at line 2077 of file parallel.c.

References CHECK, PF_Reduce(), and TimeCPU().

Here is the call graph for this function:



4.99.3.30 PF_BroadcastNumber()

```
LONG PF_BroadcastNumber (
            LONG x )  [extern]
```

Broadcasts a LONG value from the master to the all slaves.

Parameters

x	the number to be broadcast (set on the master).

Returns

the synchronised result.

Definition at line 2098 of file parallel.c.

References PF_Bcast().

Referenced by DoCheckpoint(), PF_BroadcastBuffer(), and StartVariables().

Here is the call graph for this function:

4.99.3.31 PF_BroadcastBuffer()

```
void PF_BroadcastBuffer (
            WORD ** buffer,
            LONG * length )  [extern]
```

Broadcasts a buffer from the master to all the slaves.

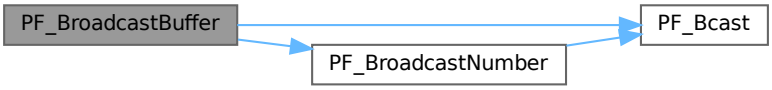
Parameters

in,out	*buffer*	on the master, the buffer to be broadcast. On the slaves, the buffer will be allocated if the length is greater than 0. The caller must free it.
in,out	*length*	on the master, the length of the buffer to be broadcast. On the slaves, it receives the length of transferred buffer. The actual transfer occurs only if the length is greater than 0.

Definition at line 2125 of file parallel.c.

References PF_Bcast(), and PF_BroadcastNumber().

Here is the call graph for this function:



4.99.3.32 PF_BroadcastString()

```
int PF_BroadcastString (
            UBYTE * str )  [extern]
```

Broadcasts a string from the master to all slaves.

Parameters

in,out	*str*	The pointer to a null-terminated string.

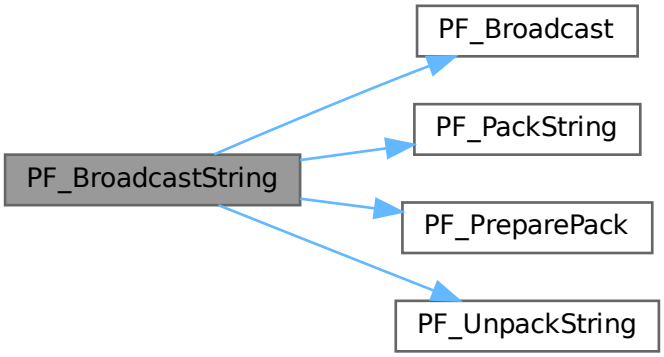
Returns

0 if OK, nonzero on error.

Definition at line 2167 of file parallel.c.

References PF_Broadcast(), PF_PackString(), PF_PreparePack(), and PF_UnpackString().

Here is the call graph for this function:



4.99.3.33 PF_BroadcastPreDollar()

```
int PF_BroadcastPreDollar (
            WORD ** dbuffer,
            LONG * newsize,
            int * numterms )  [extern]
```

Broadcasts dollar variables set as a preprocessor variables. Only the master is able to make an assignment like #$a=g; where g is an expression: only the master has an access to the expression. So, the master broadcasts the result to slaves.

The result is in ∗dbuffer of the size is ∗newsize (in number of WORDs), +1 for trailing zero. For slave newsize and numterms are output parameters.

Parameters

in,out	*dbuffer*	the buffer for a dollar variable.
in,out	*newsize*	the size of the dollar variable in WORDs.
in,out	*numterms*	the number of terms in the dollar variable.

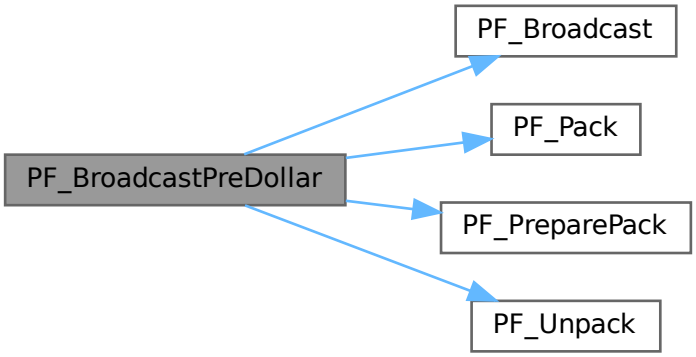
Returns

0 if OK, nonzero on error.

Definition at line 2222 of file parallel.c.

References PF_Broadcast(), PF_Pack(), PF_PreparePack(), and PF_Unpack().

Here is the call graph for this function:



4.99.3.34 PF_CollectModifiedDollars()

```
int PF_CollectModifiedDollars (
            void  )  [extern]
```

Combines modified dollar variables on the all slaves, and store them into those on the master.

The potentially modified dollar variables are given in PotModdollars, and the number of them is given by NumPot↩ Moddollars.

The current module could be executed in parallel only if all potentially modified variables are listed in ModOptdollars, otherwise the module was switched to the sequential mode.

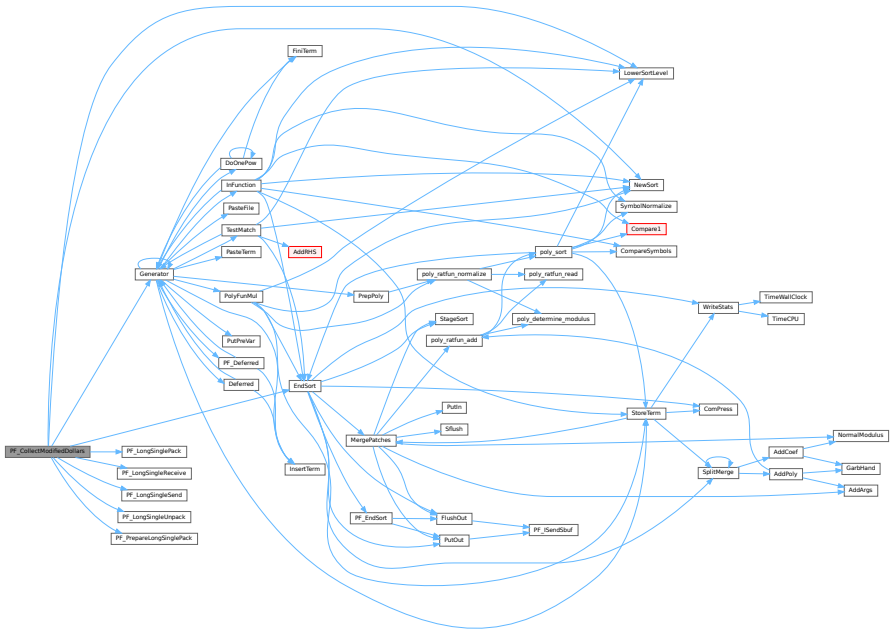
Returns

0 if OK, nonzero on error.

Definition at line 2509 of file parallel.c.

References EndSort(), Generator(), LowerSortLevel(), NewSort(), PF_LongSinglePack(), PF_LongSingleReceive(), PF_LongSingleSend(), PF_LongSingleUnpack(), PF_PrepareLongSinglePack(), VectorInit, VectorPtr, VectorReserve, and VectorSize.

Here is the call graph for this function:



4.99.3.35 PF_BroadcastModifiedDollars()

```
int PF_BroadcastModifiedDollars (
            void  )  [extern]
```

Broadcasts modified dollar variables on the master to the all slaves.

The potentially modified dollar variables are given in PotModdollars, and the number of them is given by NumPot↩Moddollars.

The current module could be executed in parallel only if all potentially modified variables are listed in ModOptdollars, otherwise the module was switched to the sequential mode. In either cases, we need to broadcast them.

Returns

0 if OK, nonzero on error.

Definition at line 2788 of file parallel.c.

References PF_LongMultiBroadcast(), and PF_PrepareLongMultiPack().

```
int PF_BroadcastExpr (
            EXPRESSIONS e,
            FILEHANDLE * file )  [extern]
```

Broadcasts an expression from the master to the all slaves.

Parameters

e	The expression to be broadcast.
file	The file in which the expression is sitting.

Returns

0 if OK, nonzero on error.

Definition at line 3552 of file parallel.c.

Referenced by PF_BroadcastRHS().

4.99.3.42 PF_BroadcastRHS()

```
int PF_BroadcastRHS (
            void  )  [extern]
```

Broadcasts expressions appearing in the right-hand side from the master to the all slaves.

Returns

0 if OK, nonzero on error.

Definition at line 3580 of file parallel.c.

References PF_BroadcastExpr().

Referenced by Processor().

Here is the call graph for this function:

4.99.3.43 PF_InParallelProcessor()

```
int PF_InParallelProcessor (
            void  )  [extern]
```

Processes expressions in the InParallel mode, i.e., dividing expressions marked by partodo over the slaves.

Returns

0 if OK, nonzero on error.

Definition at line 3627 of file parallel.c.

Referenced by Processor().

4.99.3.44 PF_SendFile()

```
int PF_SendFile (
            int to,
            FILE * fd )  [extern]
```

Sends a file to the process specified by *to*.

Parameters

to	the destination process number.
fd	the file to be sent.

Returns

the size of sent data in bytes, or -1 on error.

Definition at line 4234 of file parallel.c.

References PF_RawSend().

Referenced by DoCheckpoint().

Here is the call graph for this function:

4.99.3.46 PF_MLock()

```
void PF_MLock (
            void  )  [extern]
```

A function called by MLOCK(ErrorMessageLock) for slaves.

Definition at line 4353 of file parallel.c.

References VectorClear.

4.99.3.47 PF_MUnlock()

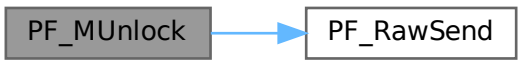
```
void PF_MUnlock (
            void  )  [extern]
```

A function called by MUNLOCK(ErrorMessageLock) for slaves.

Definition at line 4369 of file parallel.c.

References PF_RawSend(), VectorEmpty, VectorPtr, and VectorSize.

Here is the call graph for this function:



4.99.3.48 PF_WriteFileToFile()

```
LONG PF_WriteFileToFile (
            int handle,
            UBYTE * buffer,
            LONG size )  [extern]
```

Replaces WriteFileToFile() on the master and slaves.

It copies the given buffer into internal buffers if called between MLOCK(ErrorMessageLock) and MUNLOCK(Error↩MessageLock) for slaves and handle is StdOut or LogHandle, otherwise calls WriteFileToFile().

Parameters

handle	a file handle that specifies the output.
buffer	a pointer to the source buffer containing the data to be written.
size	the size of data to be written in bytes.

Returns

the actual size of data written to the output in bytes.

Definition at line 4398 of file parallel.c.

References VectorClear, VectorPtr, VectorPushBacks, and VectorSize.

4.99.3.49 PF_FlushStdOutBuffer()

```
void PF_FlushStdOutBuffer (
            void  )  [extern]
```

Explicitly Flushes the buffer for the standard output on the master, which is used if PF_ENABLE_STDOUT_↩ BUFFERING is defined.

Definition at line 4492 of file parallel.c.

References VectorClear, VectorPtr, and VectorSize.

4.99.3.50 PF_ReceiveRuntimeError()

```
void PF_ReceiveRuntimeError (
            void  )  [extern]
```

Handles a runtime error message received from another process. It ultimately calls Terminate(-1).

Definition at line 4820 of file parallel.c.

References CHECK, PF_RawRecv(), and PF_RawSend().

Referenced by PF_RecvWbuf().

4.101.1 Detailed Description

Top level pattern matching routines. More pattern matching is found in findpat.c, function.c, symmetr.c and smart.c. The last three files contain the matching inside functions. The file pattern.c contains also the very important routine Substitute. All regular pattern matching is just the finding of the pattern and indicating what are the wildcards etc. The routine Substitute does the actual removal of the pattern and replaces it by a subterm of the type SUBEXPRESSION.

Definition in file pattern.c.

4.101.2 Macro Definition Documentation

4.101.2.1 PutInBuffers

```
#define PutInBuffers(
              pow )
```

Value:

```
    AddRHS(AT.ebufnum,1); \
    *out++ = SUBEXPRESSION; \
    *out++ = SUBEXPSIZE; \
    *out++ = C->numrhs; \
    *out++ = pow; \
    *out++ = AT.ebufnum; \
    FILLSUB(out) \
    r = AT.pWorkSpace[rhs+i]; \
    if ( *r > 0 ) { \
        oldinr = r[*r]; r[*r] = 0; \
        AddNtoC(AT.ebufnum,(*r+1-ARGHEAD),(r+ARGHEAD),14); \
        r[*r] = oldinr; \
    } \
    else { \
        ToGeneral(r,buffer,1); \
        buffer[buffer[0]] = 0; \
        AddNtoC(AT.ebufnum,buffer[0]+1,buffer,15); \
    }
```

4.101.3 Function Documentation

4.101.3.1 TestMatch()

```
int TestMatch (
             PHEAD WORD * term,
             WORD * level )
```

This routine governs the pattern matching. If it decides that a substitution should be made, this can be either the insertion of a right hand side (C->rhs) or the automatic generation of terms as a result of an operation (like trace). The object to be replaced is removed from term and a subexpression pointer is inserted. If the substitution is made more than once there can be more subexpression pointers. Its number is positive as it corresponds to the level at which the C->rhs can be found in the compiler output. The subexpression pointer contains the wildcard substitution information. The power is found in *AT.TMout. For operations the subexpression pointer is negative and corresponds to an address in the array AT.TMout. In this array are then the instructions for the routine to be called and its number in the array 'Operations' The format is here: length,functionnumber,length-2 parameters

There is a certain complexity wrt repeat levels. Another complication is the poking of the wildcard values in the subexpression prototype in the compiler buffer. This was how things were done in the past with sequential FORM, but with the advent of TFORM this cannot be maintained. Now, for TFORM we make a copy of it. 7-may-2008 (JV):

We cannot yet guarantee that this has been done 100% correctly. There are errors that occur in TFORM only and that may indicate problems.

00043
00044 #include "form3.h"
00045
00046 /*
00047     #] Includes :
00048     #[ Patterns :
00049         #[ Rules :
00050
00051         There are several rules governing the allowable replacements.
00052         1:  Multi with anything but symbols or dotproducts reverts
00053             to many.
00054         2:  Each symbol can have only one (wildcard) power, so
00055             x^2*x^n? is illegal.
00056         3:  when a single vector is used it replaces all occurrences
00057             of the vector. Therefore q*q(mu) or q*q(mu) cannot occur.
00058             Also q*q cannot be done.
00059         4:  Loose vector elements are replaced with p(mu), dotproducts
00060             with p?.q.
00061         5:  p?.q? is allowed.
00062         6:  x^n? can revert to n = 0 if there is no power of x.
00063         7:  x?^n? must match some x. There could be an ambiguity otherwise.
00064
00065         #] Rules :

01970         #[ SubsInAll :          void SubsInAll()
01971
01972         This routine takes a match in id,all and stores it away in
01973         the AT.allbufnum 'compiler' buffer, after taking out the pattern.
01974         The main problem here is that id,all usually has (lots of) wildcards
01975         and their assignments are on stack and the difficult ones are in
01976         AT.ebufnum. Popping the stack while looking for more matches would
```

```
01977         loose those. Hence we have to copy them into yet another compiler
01978         buffer: AT.aebufnum. Because this may involve many matches and
01979         because the original term has only a limited number of arguments,
01980         it will pay to look for already existing ones in this buffer.
01981         (to be done later).

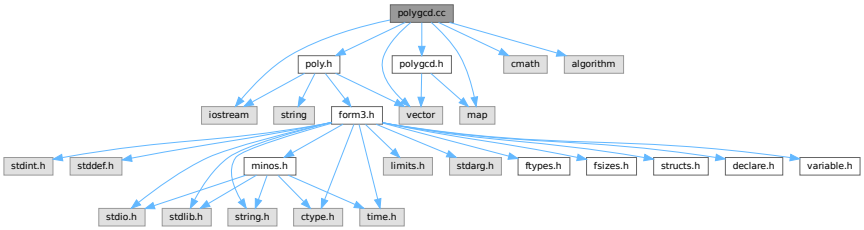
4.108 polygcd.cc File Reference

```
#include "poly.h"
#include "polygcd.h"
#include <iostream>
#include <vector>
#include <cmath>
#include <map>
#include <algorithm>
```

Include dependency graph for polygcd.cc:



Data Structures

- struct BracketInfo

Functions

- bool gcd_heuristic_possible (const poly &a)
- const poly gcd_linear_helper (const poly &a, const poly &b)

4.108.1 Detailed Description

Contains the routines for calculating greatest commons divisors of multivariate polynomials

Definition in file polygcd.cc.

4.108.2 Function Documentation

4.108.2.1 gcd_heuristic_possible()

```
bool gcd_heuristic_possible (
            const poly & a )
```

Heuristic greatest common divisor of multivariate polynomials

4.108.3 Description

Checks whether the heuristic seems possible by estimating

MAX_{terms} (coeff ^ PROD_{i=1..#vars} (pow_i+1))

and comparing this with GCD_HEURISTIC_MAX_DIGITS.

4.108.4 Notes

- For small polynomials, this consumes time and never triggers.

Definition at line 1142 of file polygcd.cc.

4.108.4.1 gcd_linear_helper()

```
const poly gcd_linear_helper (
             const poly & a,
             const poly & b )
```

Definition at line 1403 of file polygcd.cc.

4.111.1 Detailed Description

Contains methods to call the polynomial methods (written in C++) from the rest of Form (written in C). These include polynomial gcd computation, factorization and polyratfuns.

Definition in file polywrap.cc.

4.111.2 Function Documentation

4.111.2.1 poly_determine_modulus()

```
WORD poly_determine_modulus (
            PHEAD bool multi_error,
            bool is_fun_arg,
            string message )
```

Modulus for polynomial algebra

4.111.3 Description

This method determines whether polynomial algebra is done with a modulus or not. This depends on AC.ncmod. If only_funargs is set it also depends on (AC.modmode & ALSOFUNARGS).

The program terminates if the feature is not implemented. Polynomial algebra modulo M $>$ WORDSIZE in not implemented. If multi_error is set, multivariate algebra mod M is not implemented.

4.111.4 Notes

- If AC.ncmod$>$0 and only_funargs=true and AC.modmode&ALSOFUNARGS=false, AN.ncmod is set to zero, for otherwise RaisPow calculates mod M.

Definition at line 79 of file polywrap.cc.

Referenced by poly_factorize(), poly_factorize_expression(), poly_gcd(), poly_ratfun_add(), and poly_ratfun_normalize().

4.111.4.1 poly_gcd()

```
WORD * poly_gcd (
            PHEAD WORD * a,
            WORD * b,
            WORD fit )
```

Polynomial gcd

4.111.5 Description

This method calculates the greatest common divisor of two polynomials, given by two zero-terminated Form-style term lists.

4.111.6 Notes

- The result is written at newly allocated memory
- Called from ratio.c
- Calls polygcd::gcd

Definition at line 124 of file polywrap.cc.

References poly_determine_modulus().

Here is the call graph for this function:

4.111.6.1 poly_divmod()

```
WORD * poly_divmod (
              PHEAD WORD * a,
              WORD * b,
              int divmod,
              WORD fit )
```

Definition at line 203 of file polywrap.cc.

4.111.6.2 poly_div()

```
WORD * poly_div (
              PHEAD WORD * a,
              WORD * b,
              WORD fit )
```

Definition at line 437 of file polywrap.cc.

4.111.6.3 poly_rem()

```
WORD * poly_rem (
              PHEAD WORD * a,
              WORD * b,
              WORD fit )
```

Definition at line 465 of file polywrap.cc.

4.111.6.4 poly_ratfun_read()

```
void poly_ratfun_read (
             WORD * a,
             poly & num,
             poly & den )
```

Read a PolyRatFun

4.111.7 Description

This method reads a polyratfun starting at the pointer a. The resulting numerator and denominator are written in num and den. If MUSTCLEANPRF, the result is normalized.

4.111.8 Notes

- Calls polygcd::gcd

Definition at line 498 of file polywrap.cc.

Referenced by poly_ratfun_add(), and poly_ratfun_normalize().

4.111.8.1 poly_sort()

```
void poly_sort (
             PHEAD WORD * a )
```

Sort the polynomial terms

4.111.9 Description

Sorts the terms of a polynomial in Form poly(rat)fun order, i.e. lexicographical order with highest degree first.

4.111.10 Notes

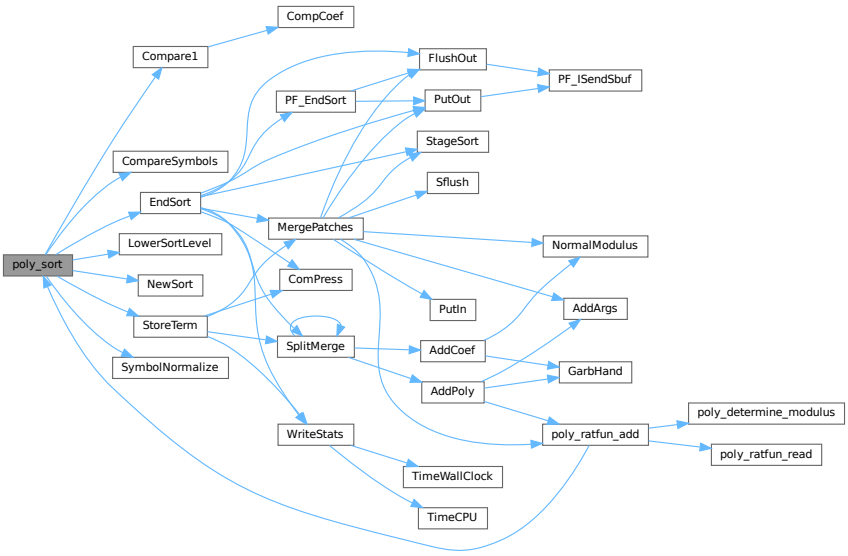
- Uses Form sort routines with custom compare

Definition at line 592 of file polywrap.cc.

References Compare1(), CompareSymbols(), EndSort(), LowerSortLevel(), NewSort(), StoreTerm(), and SymbolNormalize().

Referenced by poly_ratfun_add(), and poly_ratfun_normalize().

Here is the call graph for this function:



4.111.10.1 poly_ratfun_add()

```
WORD * poly_ratfun_add (
            PHEAD WORD * t1,
            WORD * t2 )
```

Addition of PolyRatFuns

4.111.11 Description

This method gets two pointers to polyratfuns with up to two arguments each and calculates the sum.

4.111.12 Notes

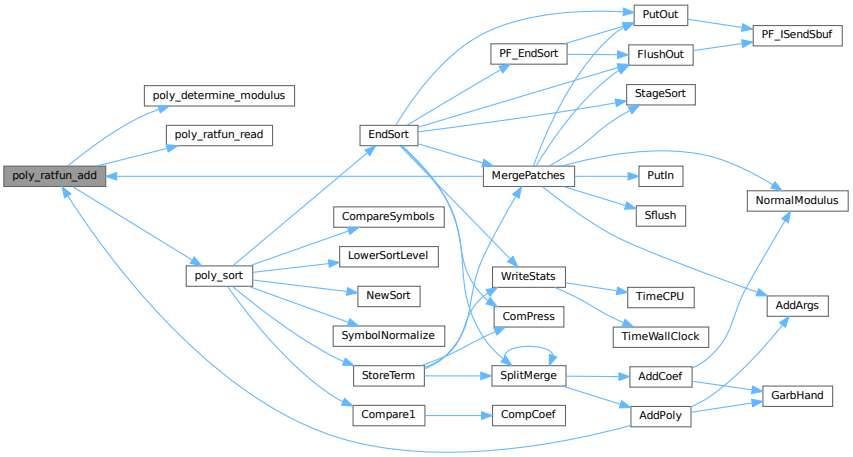
- The result is written at the workpointer
- Called from sort.c and threads.c
- Calls poly::operators and polygcd::gcd

Definition at line 635 of file polywrap.cc.

References poly_determine_modulus(), poly_ratfun_read(), and poly_sort().

Referenced by AddPoly(), and MergePatches().

Here is the call graph for this function:



4.111.12.1 poly_ratfun_normalize()

```
int poly_ratfun_normalize (
            PHEAD WORD * term )
```

Multiplication/normalization of PolyRatFuns

4.111.13 Description

This method searches a term for multiple polyratfuns and multiplies their contents. The result is properly normalized. Normalization also works for terms with a single polyratfun.

4.111.14 Notes

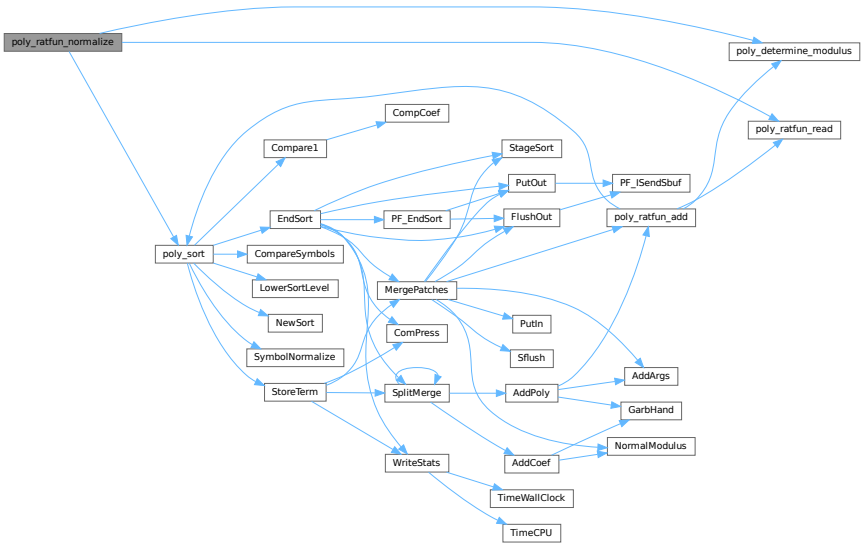
- The result overwrites the original term
- Called from proces.c
- Calls poly::operators and polygcd::gcd

Definition at line 771 of file polywrap.cc.

References poly_determine_modulus(), poly_ratfun_read(), and poly_sort().

Referenced by PolyFunMul(), and PrepPoly().

Here is the call graph for this function:



4.111.14.1 poly_fix_minus_signs()

```
void poly_fix_minus_signs (
            factorized_poly & a )
```

Definition at line 923 of file polywrap.cc.

4.111.14.2 poly_factorize()

```
WORD * poly_factorize (
            PHEAD WORD * argin,
            WORD * argout,
            bool with_arghead,
            bool is_fun_arg )
```

Factorization of function arguments / dollars

4.111.15 Description

This method factorizes a Form style argument or zero-terminated term list.

4.111.16 Notes

- Called from poly_factorize_{argument,dollar}
- Calls polyfact::factorize

Definition at line 988 of file polywrap.cc.

References poly_determine_modulus().

Referenced by poly_factorize_argument(), and poly_factorize_dollar().

Here is the call graph for this function:

4.111.16.1 poly_factorize_argument()

```
int poly_factorize_argument (
              PHEAD WORD * argin,
              WORD * argout )
```

Factorization of function arguments

4.111.17 Description

This method factorizes the Form-style argument argin.

4.111.18 Notes

- The result is written at argout
- Called from argument.c
- Calls poly_factorize

Definition at line 1114 of file polywrap.cc.

References poly_factorize().

Here is the call graph for this function:

4.111.18.1 poly_factorize_dollar()

```
WORD * poly_factorize_dollar (
             PHEAD WORD * argin )
```

Factorization of dollar variables

4.111.19 Description

This method factorizes a dollar variable.

4.111.20 Notes

- The result is written at newly allocated memory.
- Called from dollar.c
- Calls poly_factorize

Definition at line 1148 of file polywrap.cc.

References poly_factorize().

Here is the call graph for this function:

4.111.20.1 poly_factorize_expression()

```
int poly_factorize_expression (
            EXPRESSIONS expr )
```

Factorization of expressions

4.111.21 Description

This method factorizes an expression.

4.111.22 Notes

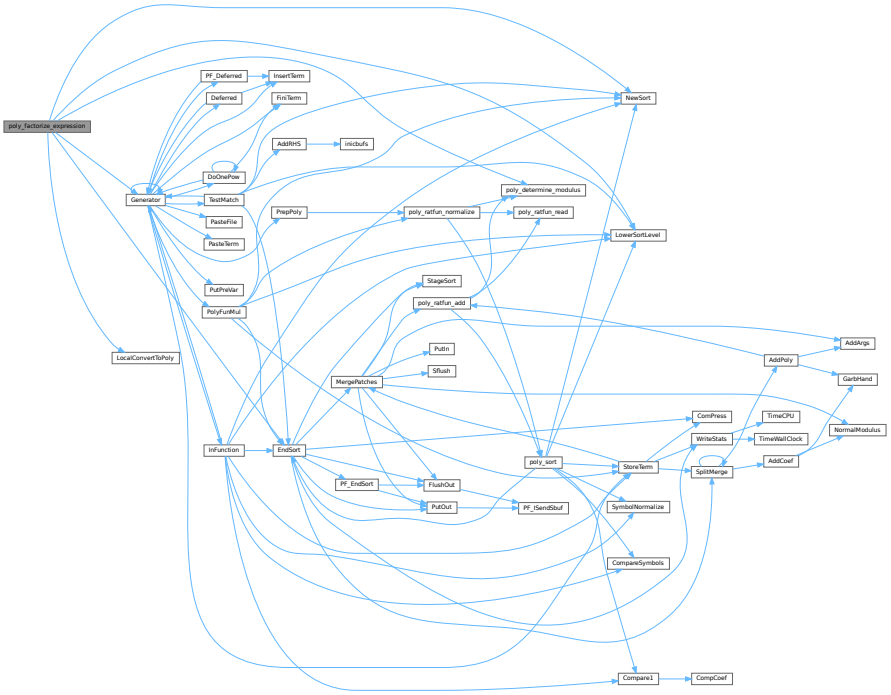
- The result overwrites the input expression
- Called from proces.c
- Calls polyfact::factorize

Definition at line 1180 of file polywrap.cc.

References EndSort(), Generator(), FiLe::handle, LocalConvertToPoly(), LowerSortLevel(), NewSort(), and poly_determine_modulus().

Referenced by PF_Processor(), and Processor().

Here is the call graph for this function:



4.111.22.1 poly_unfactorize_expression()

```
int poly_unfactorize_expression (
            EXPRESSIONS expr )
```

Unfactorization of expressions

4.111.23 Description

This method expands a factorized expression.

4.111.24 Notes

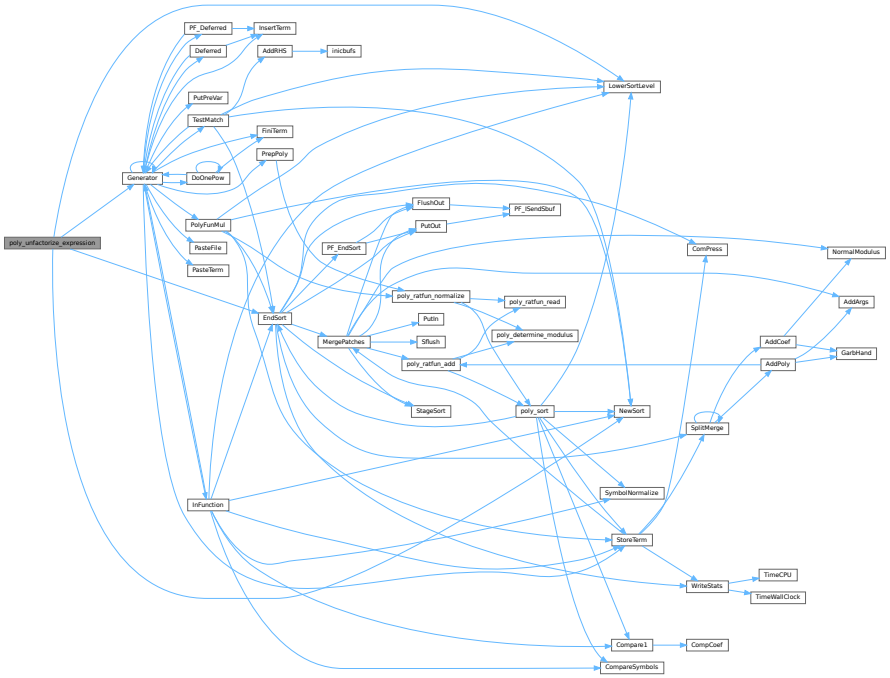
- The result overwrites the input expression
- Called from proces.c

Definition at line 1545 of file polywrap.cc.

References EndSort(), Generator(), FiLe::handle, LowerSortLevel(), and NewSort().

Referenced by PF_Processor(), and Processor().

Here is the call graph for this function:



4.111.24.1 poly_inverse()

```
WORD * poly_inverse (
              PHEAD WORD * arga,
              WORD * argb )
```

Definition at line 1757 of file polywrap.cc.

4.111.24.2 poly_mul()

```
WORD * poly_mul (
              PHEAD WORD * a,
              WORD * b )
```

Definition at line 1962 of file polywrap.cc.

4.111.24.3 poly_free_poly_vars()

```
void poly_free_poly_vars (
              PHEAD const char * text )
```

Definition at line 2028 of file polywrap.cc.

4.111.25 Variable Documentation

4.111.25.1 POLYWRAP_DENOMPOWER_INCREASE_FACTOR

```
const int POLYWRAP_DENOMPOWER_INCREASE_FACTOR = 2
```

Definition at line 52 of file polywrap.cc.

4.113.1 Detailed Description

Contains definitions for signals used/intercepted in FORM.

Some systems (especially LINUX) have not enough signals available so some of the (!documented!) signals are not defined. This file contains the definition of all signals used in the program. If the signal is not defined we define it as unused (>NSIG).

The include of signal.h must be first, before we try to define undefined signals.

Definition in file portsignals.h.

4.113.2 Macro Definition Documentation

4.113.2.1 FATAL_SIG_ERROR

```
#define FATAL_SIG_ERROR 4
```

Definition at line 47 of file portsignals.h.

4.113.2.2 NSIG

```
#define NSIG (1024)
```

Definition at line 53 of file portsignals.h.

4.113.2.3 SIGSEGV

```
#define SIGSEGV (NSIG+1)
```

Definition at line 57 of file portsignals.h.

4.113.2.4 SIGFPE

```
#define SIGFPE (NSIG+2)
```

Definition at line 60 of file portsignals.h.

4.113.2.5 SIGILL

```
#define SIGILL (NSIG+3)
```

Definition at line 63 of file portsignals.h.

4.113.2.6 SIGEMT

```
#define SIGEMT (NSIG+4)
```

4.115.1 Detailed Description

This is the preprocessor and all its routines.

Definition in file pre.c.

4.115.2 Macro Definition Documentation

4.115.2.1 STRINGIFY

```
#define STRINGIFY(
              x ) STRINGIFY__(x)
```

Definition at line 4342 of file pre.c.

4.115.2.2 STRINGIFY__

```
#define STRINGIFY__(
              x ) #x
```

Definition at line 4343 of file pre.c.

4.115.2.3 SKIPBUFSIZE

```
#define SKIPBUFSIZE 20
```

Definition at line 4466 of file pre.c.

4.115.2.4 KILL

```
#define KILL "kill"
```

Definition at line 5686 of file pre.c.

4.115.2.5 KILLALL

```
#define KILLALL "killall"
```

Definition at line 5687 of file pre.c.

4.115.2.6 DAEMON

```
#define DAEMON "daemon"
```

Definition at line 5688 of file pre.c.

4.115.2.7 SHELL

```
#define SHELL "shell"
```

Definition at line 5689 of file pre.c.

4.115.2.8 STDERR

```
#define STDERR "stderr"
```

Definition at line 5690 of file pre.c.

4.115.2.9 TRUE_EXPR

```
#define TRUE_EXPR "true"
```

Definition at line 5692 of file pre.c.

4.115.2.10 FALSE_EXPR

```
#define FALSE_EXPR "false"
```

Definition at line 5693 of file pre.c.

4.115.2.11 NOSHELL

```
#define NOSHELL "noshell"
```

Definition at line 5694 of file pre.c.

4.115.2.12 TERMINAL

```
#define TERMINAL "terminal"
```

Definition at line 5695 of file pre.c.

4.115.3 Function Documentation

4.115.3.1 GetInput()

```
UBYTE GetInput (
            void  )
```

Definition at line 138 of file pre.c.

4.115.3.2 ClearPushback()

```
void ClearPushback (
            void  )
```

Definition at line 167 of file pre.c.

4.115.3.3 GetChar()

```
UBYTE GetChar (
            int level )
```

Definition at line 185 of file pre.c.

4.115.3.4 CharOut()

```
void CharOut (
            UBYTE c )
```

Definition at line 495 of file pre.c.

4.115.3.5 UnsetAllowDelay()

```
void UnsetAllowDelay (
            void  )
```

Definition at line 516 of file pre.c.

4.115.3.6 GetPreVar()

```
UBYTE * GetPreVar (
            UBYTE * name,
            int flag )
```

Definition at line 542 of file pre.c.

4.115.3.7 PutPreVar()

```
int PutPreVar (
            UBYTE * name,
            UBYTE * value,
            UBYTE * args,
            int mode )
```

Inserts/Updates a preprocessor variable in the name administration.

Parameters

name	Character string with the variable name.
value	Character string with a possible value. Special case: if this argument is zero, then we have no value. Note: This is different from having an empty argument! This should only occur when the name starts with a ?
args	Character string with possible arguments.
mode	=0: always create a new name entry, =1: try to do a redefinition if possible.

Returns

Index of used entry in name list.

Definition at line 724 of file pre.c.

Referenced by ClearOptimize(), Generator(), Optimize(), PF_BroadcastRedefinedPreVars(), StartVariables(), and TheDefine().

4.115.3.8 PopPreVars()

```
void PopPreVars (
            int tonumber )
```

Definition at line 826 of file pre.c.

4.115.3.9 IniModule()

```
void IniModule (
            int type )
```

Definition at line 841 of file pre.c.

4.115.3.10 IniSpecialModule()

```
void IniSpecialModule (
            int type )
```

Definition at line 943 of file pre.c.

4.115.3.11 PreProcessor()

```
void PreProcessor (
            void  )
```

Definition at line 953 of file pre.c.

4.115.3.12 PreProInstruction()

```
int PreProInstruction (
            void  )
```

Definition at line 1172 of file pre.c.

4.115.3.13 LoadInstruction()

```
int LoadInstruction (
            int mode )
```

Definition at line 1269 of file pre.c.

4.115.3.14 LoadStatement()

```
int LoadStatement (
            int type )
```

Definition at line 1472 of file pre.c.

4.115.3.15 ExpandTripleDots()

```
int ExpandTripleDots (
            int par )
```

Definition at line 1610 of file pre.c.

4.115.3.16 FindKeyWord()

```
KEYWORD * FindKeyWord (
            UBYTE * theword,
            KEYWORD * table,
            int size )
```

Definition at line 1978 of file pre.c.

4.115.3.17 FindInKeyWord()

```
KEYWORD * FindInKeyWord (
            UBYTE * theword,
            KEYWORD * table,
            int size )
```

Definition at line 2009 of file pre.c.

4.115.3.18 TheDefine()

```
int TheDefine (
            UBYTE * s,
            int mode )
```

Preprocessor assignment. Possible arguments and values are treated and the new preprocessor variable is put into the name administration.

Parameters

s	Pointer to the character string following the preprocessor command.
mode	Bitmask. 0-bit clear: always create a new name entry, 0-bit set: try to redefine an existing name, 1-bit set: ignore preprocessor if/switch status.

Returns

zero: no errors, negative number: errors.

Definition at line 2039 of file pre.c.

References PutPreVar().

Here is the call graph for this function:

4.115.3.19 DoCommentChar()

```
int DoCommentChar (
            UBYTE * s )
```

Definition at line 2112 of file pre.c.

4.115.3.20 DoPreAssign()

```
int DoPreAssign (
            UBYTE * s )
```

Definition at line 2143 of file pre.c.

4.115.3.21 DoDefine()

```
int DoDefine (
            UBYTE * s )
```

Definition at line 2174 of file pre.c.

4.115.3.22 DoRedefine()

```
int DoRedefine (
            UBYTE * s )
```

Definition at line 2184 of file pre.c.

4.115.3.23 ClearMacro()

```
int ClearMacro (
            UBYTE * name )
```

Definition at line 2196 of file pre.c.

4.115.3.24 TheUndefine()

```
int TheUndefine (
            UBYTE * name )
```

Definition at line 2224 of file pre.c.

4.115.3.25 DoUndefine()

```
int DoUndefine (
            UBYTE * s )
```

Definition at line 2278 of file pre.c.

4.115.3.26 DoInclude()

```
int DoInclude (
            UBYTE * s )
```

Definition at line 2330 of file pre.c.

4.115.3.27 DoReverseInclude()

```
int DoReverseInclude (
            UBYTE * s )
```

Definition at line 2337 of file pre.c.

4.115.3.28 Include()

```
int Include (
            UBYTE * s,
            int type )
```

Definition at line 2344 of file pre.c.

4.115.3.29 DoPreExchange()

```
int DoPreExchange (
            UBYTE * s )
```

Definition at line 2505 of file pre.c.

4.115.3.30 DoCall()

```
int DoCall (
            UBYTE * s )
```

Definition at line 2566 of file pre.c.

4.115.3.31 DoDebug()

```
int DoDebug (
            UBYTE * s )
```

Definition at line 2742 of file pre.c.

4.115.3.32 DoTerminate()

```
int DoTerminate (
            UBYTE * s )
```

Definition at line 2779 of file pre.c.

4.115.3.33 DoContinueDo()

```
int DoContinueDo (
            UBYTE * s )
```

Jumps forward to the corresponding `#enddo` of the specified number of outer `#do` loops.

Syntax:

```
#continuedo [<number>=1]
```

If `number` is omitted, it defaults to 1. If `number` is zero then the instruction has no effect.

Definition at line 2813 of file pre.c.

4.115.3.34 DoDo()

```
int DoDo (
            UBYTE * s )
```

Definition at line 2877 of file pre.c.

4.115.3.35 DoBreakDo()

```
int DoBreakDo (
            UBYTE * s )
```

Definition at line 3092 of file pre.c.

4.115.3.36 DoElse()

```
int DoElse (
            UBYTE * s )
```

Definition at line 3170 of file pre.c.

4.115.3.37 DoElseif()

```
int DoElseif (
            UBYTE * s )
```

Definition at line 3207 of file pre.c.

4.115.3.38 DoEnddo()

```
int DoEnddo (
            UBYTE * s )
```

Definition at line 3242 of file pre.c.

4.115.3.39 DoEndif()

```
int DoEndif (
            UBYTE * s )
```

Definition at line 3388 of file pre.c.

4.115.3.40 DoEndprocedure()

```
int DoEndprocedure (
            UBYTE * s )
```

Definition at line 3416 of file pre.c.

4.115.3.41 DoIf()

```
int DoIf (
            UBYTE * s )
```

Definition at line 3443 of file pre.c.

4.115.3.42 DoIfdef()

```
int DoIfdef (
            UBYTE * s,
            int par )
```

Definition at line 3467 of file pre.c.

4.115.3.43 DoIfydef()

```
int DoIfydef (
            UBYTE * s )
```

Definition at line 3492 of file pre.c.

4.115.3.44 DoIfndef()

```
int DoIfndef (
            UBYTE * s )
```

Definition at line 3502 of file pre.c.

4.115.3.45 DoInside()

```
int DoInside (
            UBYTE * s )
```

Definition at line 3527 of file pre.c.

4.115.3.46 DoEndInside()

```
int DoEndInside (
            UBYTE * s )
```

Definition at line 3620 of file pre.c.

4.115.3.47 DoMessage()

```
int DoMessage (
            UBYTE * s )
```

Definition at line 3752 of file pre.c.

04069
04070         We have to read this procedure into a buffer.
04071         The only complications are:
04072         1: we have to seek through the file to do this efficiently
04073            the file operations under VMS cannot do this properly
04074            (unless we use the proper ANSI structs?)
04075            This is the reason why we read whole input files under VMS.
04076         2: what to do when the same name is used twice.
04077         Note that we have to do the reading without substitution of
04078         preprocessor variables.

07575         #] ConstructName :
07576         #[ DoUse :
07577
07578         Routine makes (inside the confines of the current namespace)
07579         a list of variables that are excluded from the namespace.
07580         Once the namespace is ended, the list is removed.
07581         The list can include names of variables, dollars and procedures.
07582         Preprocessor variables are excluded from the namespace. Their
07583         inclusion would be too complicated for the input streams.
07584         Note that the preprocessor variables that are arguments in a #do
07585         or in a procedure are on a stack and should not cause problems.
07586         Names of variables can be just that.
07587         Names of $-variables are also straightforward.
07588         Names of procedures should be preceeded by a # character.
07589         Names of files (like in #include) should be enclosed by <>.
07590         The names are stored in a balanced tree. Each namespace may have
07591         its own tree. The toplevel (no namespace) does not allow a #use.

4.117.1 Detailed Description

Contains the central terms processor routines. This is the core of the virtual machine. All other files are to help these routines.

Definition in file proces.c.

4.117.2 Macro Definition Documentation

4.117.2.1 DONE

```
#define DONE(
              x ) { retvalue = x; goto Done; }
```

TestSub hunts for subexpression pointers. If one is found its power is given in AN.TeSuOut. and the returnvalue is 'expressionnumber'. If the expression number is negative it is an expression on disk.

In addition this routine tries to locate subexpression pointers in functions. It also notices that action must be taken with any of the special functions.

Parameters

term	The term in which TestSub hunts for potential action
level	The number of the 'level' in the compiler buffer.

Returns

The number of the (sub)expression that was encountered.

Other values that are returned are in AN.TeSuOut, AR.TePos, AT.TMbuff, AN.TeInFun, AN.Frozen, AT.TMaddr

The level in the compiler buffer is more or less the number of the statement in the module. Hence it refers to the element in the lhs array.

This routine is one of the most important routines in FORM.

Definition at line 701 of file proces.c.

4.117.3 Function Documentation

4.117.3.1 Processor()

```
int Processor (
             void  )
```

This is the central processor. It accepts a stream of Expressions which is accessed by calls to GetTerm. The expressions reside either in AR.infile or AR.hidefile The definitions of an expression are seen as an id-statement, so the primary Expressions should be written to the system of scratch files as single terms with an expression pointer. Each expression is terminated with a zero and the whole is terminated by two zeroes.

The routine DoExecute should determine whether results are to be printed, should revert the scratch I/O directions etc. In principle it is DoExecute that calls Processor.

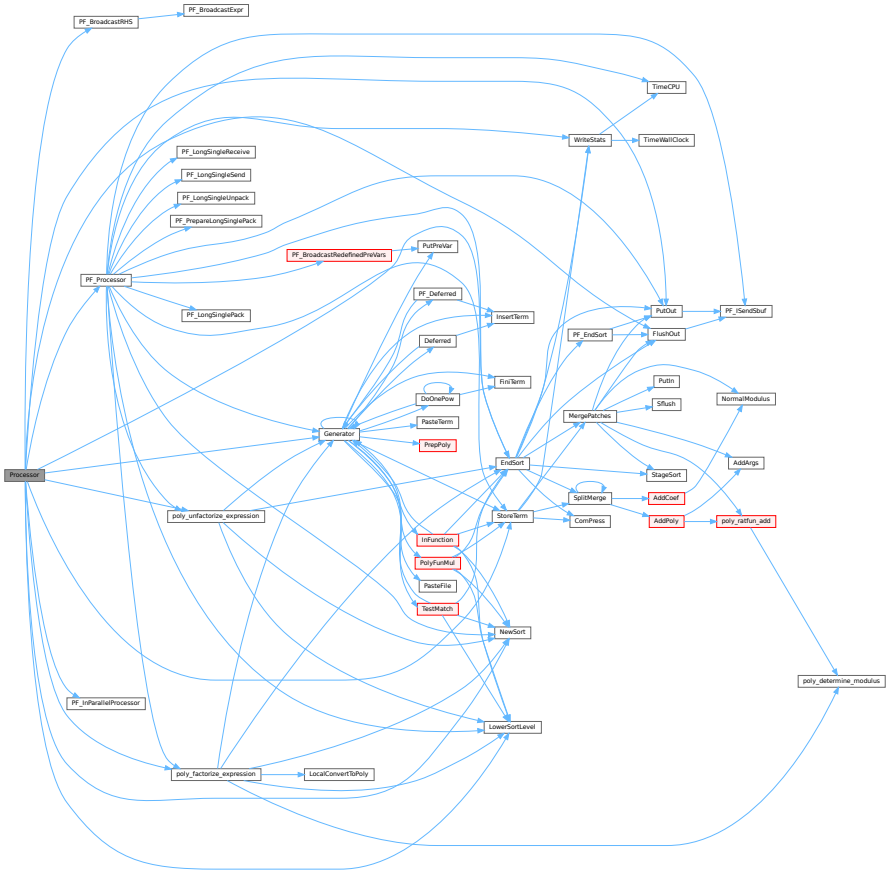
Returns

if everything OK: 0. Otherwise error. The preprocessor may continue with compilation though. Really fatal errors should return on the spot by calling Terminate.

Definition at line 64 of file proces.c.

References CbUf::Buffer, EndSort(), FlushOut(), Generator(), CbUf::lhs, LowerSortLevel(), NewSort(), PF_BroadcastRHS(), PF_InParallelProcessor(), PF_Processor(), CbUf::Pointer, poly_factorize_expression(), poly_unfactorize_expression(), PutOut(), CbUf::rhs, and StoreTerm().

Here is the call graph for this function:



4.117.3.2 TestSub()

```
WORD TestSub (
            PHEAD WORD * term,
            WORD level )
```

Definition at line 703 of file proces.c.

4.117.3.3 InFunction()

```
int InFunction (
              PHEAD WORD * term,
              WORD * termout )
```

Makes the replacement of the subexpression with the number 'replac' in a function argument. Additional information is passed in some of the AR, AN, AT variables.

Parameters

term	The input term
termout	The output term

Returns

0: everything is fine, Negative: fatal, Positive: error.

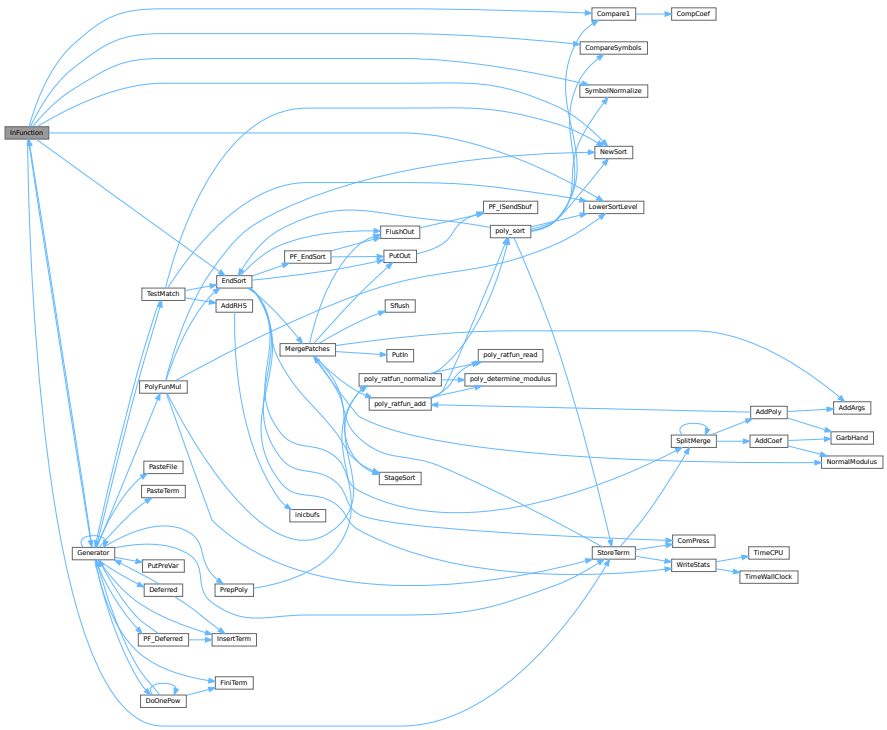
Special attention should be given to nested functions!

Definition at line 2180 of file proces.c.

References Compare1(), CompareSymbols(), EndSort(), Generator(), LowerSortLevel(), NewSort(), StoreTerm(), and SymbolNormalize().

Referenced by Generator().

Here is the call graph for this function:



4.117.3.4 InsertTerm()

```
int InsertTerm (
              PHEAD WORD * term,
              WORD replac,
              WORD extractbuff,
              WORD * position,
              WORD * termout,
              WORD tepos )
```

Puts the terms 'term' and 'position' together into a single legal term in termout. replac is the number of the subexpression that should be replaced. It must be a positive term. When action is needed in the argument of a function all terms in that argument are dealt with recursively. The subexpression is sorted. Only one subexpression is done at a time this way.

Parameters

term	the input term
replac	number of the subexpression pointer to replace
extractbuff	number of the compiler buffer replac refers to
position	position from where to take the term in the compiler buffer
termout	the output term
tepos	offset in term where the subexpression is.

Returns

Normal conventions (OK = 0).

Definition at line 2749 of file proces.c.

Referenced by Deferred(), Generator(), and PF_Deferred().

4.117.3.5 PasteFile()

```
LONG PasteFile (
              PHEAD WORD number,
              WORD * accum,
              POSITION * position,
              WORD ** accfill,
              RENUMBER renumber,
              WORD * freeze,
              WORD nexpr )
```

Gets a term from stored expression expr and puts it in the accumulator at position number. It returns the length of the term that came from file.

Parameters

number	number of partial terms to skip in accum
accum	the accumulator
position	file position from where to get the stored term
accfill	returns tail position in accum
renumber	the renumber struct for the variables in the stored expression
freeze	information about if we need only the contents of a bracket
nexpr	the number of the stored expression

Returns

Normal conventions (OK = 0).

Definition at line 2885 of file proces.c.

Referenced by Generator().

4.117.3.6 PasteTerm()

```
WORD * PasteTerm (
              PHEAD WORD number,
              WORD * accum,
              WORD * position,
              WORD times,
              WORD divby )
```

Puts the term at position in the accumulator accum at position 'number+1'. if times $>$ 0 the coefficient of this term is multiplied by times/divby.

Parameters

number	The number of term fragments in accum that should be skipped
accum	The accumulator of term fragments
position	A position in (typically) a compiler buffer from where a (piece of a) term comes.
times	Multiply the result by this
divby	Divide the result by this.

This routine is typically used when we have to replace a (sub)expression pointer by a power of a (sub)expression. This uses mostly a binomial expansion and the new term is the old term multiplied one by one by terms of the new expression. The factors times and divby keep track of the binomial coefficient. Once this is complete, the routine FiniTerm will make the contents of the accumulator into a proper term that still needs to be normalized.

Definition at line 3009 of file proces.c.

Referenced by Generator().

4.117.3.7 FiniTerm()

```
int FiniTerm (
              PHEAD WORD * term,
              WORD * accum,
              WORD * termout,
              WORD number,
              WORD tepos )
```

Concatenates the contents of the accumulator into a single legal term, which replaces the subexpression pointer

Parameters

term	the input term with the (sub)expression subterm
accum	the accumulator with the term fragments
termout	the location where the output should be written
number	the number of term fragments in the accumulator
tepos	the position of the subterm in term to be replaced

Definition at line 3076 of file proces.c.

Referenced by DoOnePow(), and Generator().

4.117.3.8 Generator()

```
int Generator (
              PHEAD WORD * term,
              WORD level )
```

The heart of the program. Here the expansion tree is set up in one giant recursion

Parameters

term	the input term. may be overwritten
level	the level in the compiler buffer (number of statement)

Returns

Normal conventions (OK = 0).

The routine looks first whether there are unsubstituted (sub)expressions. If so, one of them gets inserted term by term and the new term is used in a renewed call to Generator. If there are no (sub)expressions, the term is normalized, the compiler level is raised (next statement) and the program looks what type of statement this is. If this is a special statement it is either treated on the spot or the appropriate routine is called. If it is a substitution, the pattern matcher is called (TestMatch) which tells whether there was a match. If so we need to call TestSub again to test for (sub)expressions. If we run out of levels, the term receives a final treatment for modulus calculus and/or brackets and is then sent off to the sorting routines.

Definition at line 3275 of file proces.c.

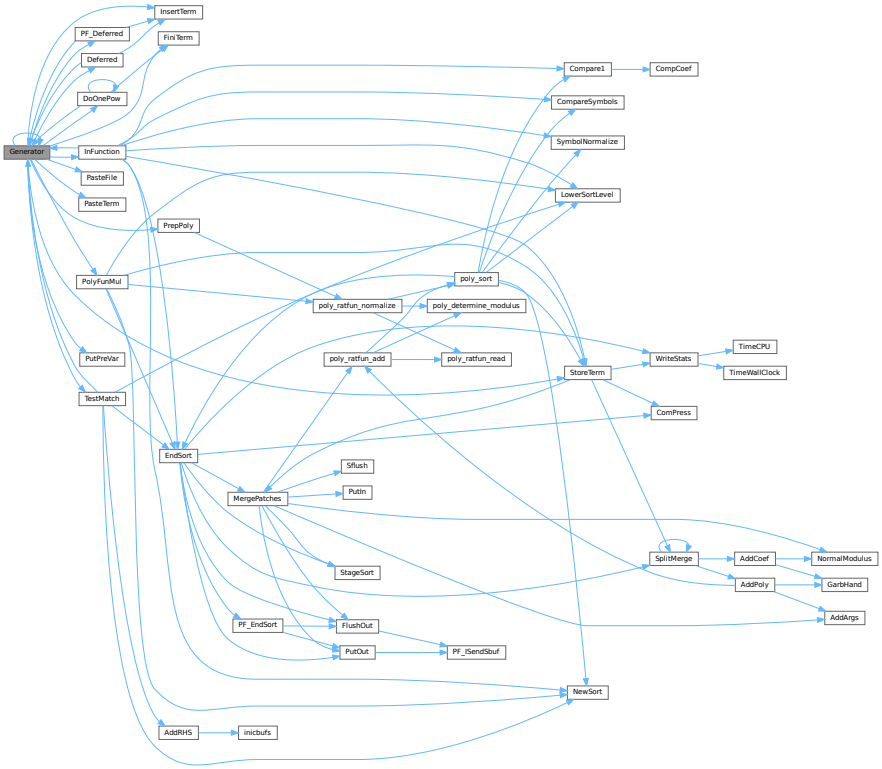
Here is the call graph for this function:



4.117.3.9 DoOnePow()

```
int DoOnePow (
            PHEAD WORD * term,
            WORD power,
            WORD nexp,
            WORD * accum,
            WORD * aa,
            WORD level,
            WORD * freeze )
```

Routine gets one power of an expression in the scratch system. If there are more powers needed there will be a recursion.

No attempt is made to use binomials because we have no information about commuting properties.

There is a searching for the contents of brackets if needed. This searching may be rather slow because of the single links.

Parameters

term	is the term we are adding to.
power	is the power of the expression that we need.
nexp	is the number of the expression.
accum	is the accumulator of terms. It accepts the termfragments that are made into a proper term in FiniTerm

Parameters

aa	points to the start of the entire accumulator. In ∗aa we store the number of term fragments that are in the accumulator.
level	is the current depth in the tree of statements. It is needed to continue to the next operation/substitution with each generated term
freeze	is the pointer to the bracket information that should be matched.

Definition at line 4653 of file proces.c.

References DoOnePow(), FiniTerm(), Generator(), and FiLe::handle.

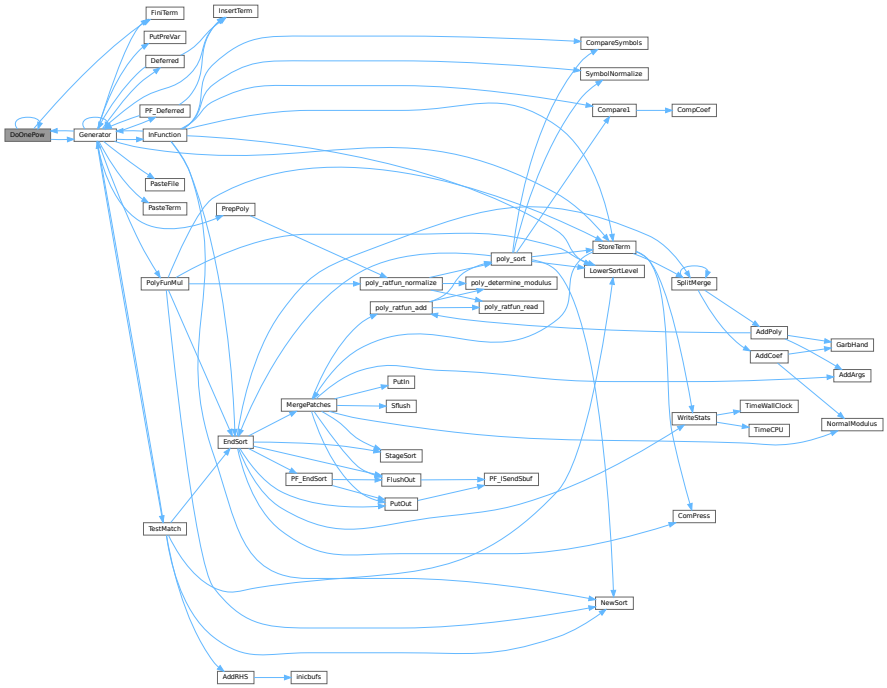
Here is the call graph for this function:



4.117.3.10 Deferred()

```
int Deferred (
            PHEAD WORD * term,
            WORD level )
```

Picks up the deferred brackets. These are the bracket contents of which we postpone the reading when we use the 'Keep Brackets' statement. These contents are multiplying the terms just before they are sent to the sorting system. Special attention goes to having it thread-safe We have to lock positioning the file and reading it in a thread specific buffer.

Parameters

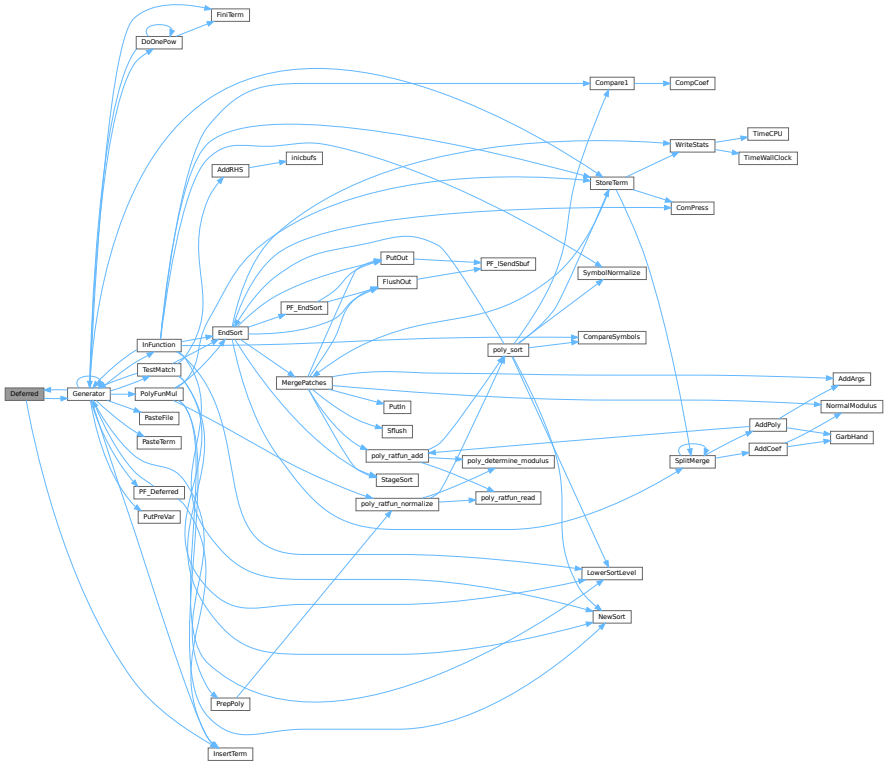
term	The term that must be multiplied by the contents of the current bracket
level	The compiler level. This is needed because after multiplying term by term we call Generator again.

Definition at line 4876 of file proces.c.

References Generator(), and InsertTerm().

Referenced by Generator().

Here is the call graph for this function:



4.117.3.11 PrepPoly()

```
int PrepPoly (
            PHEAD WORD * term,
            WORD par )
```

Routine checks whether the count of function AR.PolyFun is zero or one. If it is one and it has one scalarlike argument the coefficient of the term is pulled inside the argument. If the count is zero a new function is made with the coefficient as its only argument. The function should be placed at its proper position.

When this function is active it places the PolyFun as last object before the coefficient. This is needed because otherwise the compress algorithm has problems in MergePatches.

The bracket routine should also place the PolyFun at a comparable spot. The compression should then stop at the PolyFun. It doesn't really have to stop when writing the final result but this may be too complicated.

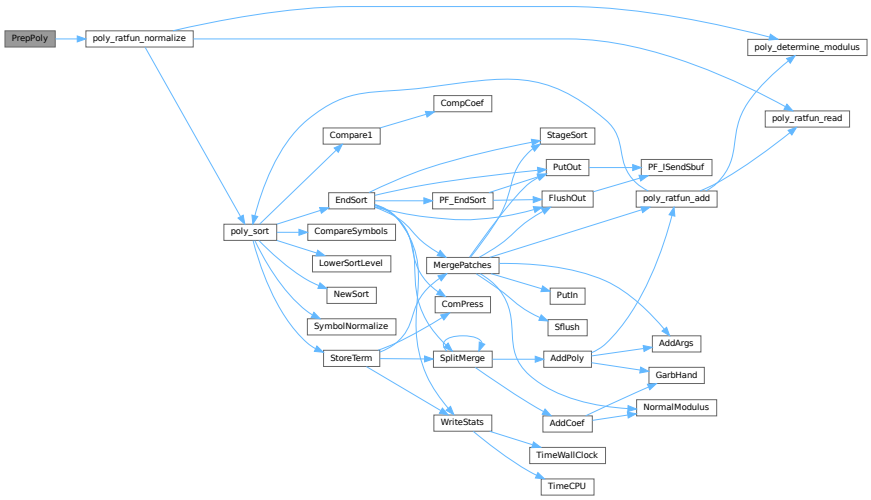
The parameter par tells whether we are at groundlevel or inside a function or dollar variable.

Definition at line 5004 of file proces.c.

References poly_ratfun_normalize().

Referenced by Generator().

Here is the call graph for this function:



4.117.3.12 PolyFunMul()

```
int PolyFunMul (
            PHEAD WORD * term )
```

Multiplies the arguments of multiple occurrences of the polyfun. In this routine we do the original PolyFun with one argument only. The PolyRatFun (PolyFunType = 2) is done in a dedicated routine in the file polywrap.cc The new result is written over the old result.

Parameters

term	It contains the input term and later the output.

Returns

Normal conventions (OK = 0).

Definition at line 5394 of file proces.c.

References EndSort(), LowerSortLevel(), NewSort(), poly_ratfun_normalize(), and StoreTerm().

Referenced by Generator().

4.119.1 Detailed Description

A variety of routines: The ratio command for partial fractioning (rather old. Schoonschip inheritance) The sum routines.

Definition in file ratio.c.

4.119.2 Function Documentation

4.119.2.1 RatioFind()

```
int RatioFind (
            PHEAD WORD * term,
            WORD * params )
```

Definition at line 62 of file ratio.c.

4.119.2.2 RatioGen()

```
int RatioGen (
            PHEAD WORD * term,
            WORD * params,
            WORD num,
            WORD level )
```

Definition at line 170 of file ratio.c.

4.119.2.3 BinomGen()

```
int BinomGen (
            PHEAD WORD * term,
            WORD level,
            WORD ** tstops,
            WORD x1,
            WORD x2,
            WORD pow1,
            WORD pow2,
            WORD sign,
            UWORD * coef,
            WORD ncoef )
```

Definition at line 320 of file ratio.c.

4.119.2.4 DoSumF1()

```
int DoSumF1 (
            PHEAD WORD * term,
            WORD * params,
            WORD replac,
            WORD level )
```

Definition at line 395 of file ratio.c.

4.119.2.5 Glue()

```
int Glue (
            PHEAD WORD * term1,
            WORD * term2,
            WORD * sub,
            WORD insert )
```

Definition at line 461 of file ratio.c.

4.119.2.6 DoSumF2()

```
int DoSumF2 (
            PHEAD WORD * term,
            WORD * params,
            WORD replac,
            WORD level )
```

Definition at line 520 of file ratio.c.

4.119.2.7 GCDfunction()

```
int GCDfunction (
            PHEAD WORD * term,
            WORD level )
```

Definition at line 609 of file ratio.c.

4.119.2.8 GCDfunction3()

```
WORD * GCDfunction3 (
            PHEAD WORD * in1,
            WORD * in2 )
```

Definition at line 1147 of file ratio.c.

4.119.2.9 PutExtraSymbols()

```
WORD * PutExtraSymbols (
            PHEAD WORD * in,
            WORD startebuf,
            int * actionflag )
```

Definition at line 1249 of file ratio.c.

4.119.2.10 TakeExtraSymbols()

```
WORD * TakeExtraSymbols (
            PHEAD WORD * in,
            WORD startebuf )
```

Definition at line 1278 of file ratio.c.

4.119.2.11 MultiplyWithTerm()

```
WORD * MultiplyWithTerm (
            PHEAD WORD * in,
            WORD * term,
            WORD par )
```

Definition at line 1317 of file ratio.c.

4.119.2.12 TakeContent()

```
WORD * TakeContent (
            PHEAD WORD * in,
            WORD * term )
```

Implements part of the old ExecArg in which we take common factors from arguments with more than one term. Here the input is a sequence of terms in 'in' and the answer is a content-free sequence of terms. This sequence has been allocated by the Malloc1 routine in a call to EndSort, unless the expression was already content-free. In that case the input pointer is returned. The content is returned in term. This is supposed to be a separate allocation, made by TermMalloc in the calling routine.

Definition at line 1382 of file ratio.c.

References GetModInverses().

Here is the call graph for this function:

4.119.2.13 MergeSymbolLists()

```
int MergeSymbolLists (
            PHEAD WORD * old,
            WORD * extra,
            int par )
```

Definition at line 1830 of file ratio.c.

4.119.2.14 MergeDotproductLists()

```
int MergeDotproductLists (
            PHEAD WORD * old,
            WORD * extra,
            int par )
```

Definition at line 1950 of file ratio.c.

4.119.2.15 CreateExpression()

```
WORD * CreateExpression (
            PHEAD WORD nexp )
```

Definition at line 2077 of file ratio.c.

4.119.2.16 GCDterms()

```
int GCDterms (
            PHEAD WORD * term1,
            WORD * term2,
            WORD * termout )
```

Definition at line 2133 of file ratio.c.

4.119.2.17 ReadPolyRatFun()

```
int ReadPolyRatFun (
            PHEAD WORD * term )
```

Definition at line 2321 of file ratio.c.

4.119.2.18 FromPolyRatFun()

```
int FromPolyRatFun (
            PHEAD WORD * fun,
            WORD ** numout,
            WORD ** denout )
```

Definition at line 2440 of file ratio.c.

4.119.2.19 TakeSymbolContent()

```
WORD * TakeSymbolContent (
            PHEAD WORD * in,
            WORD * term )
```

Implements part of the old ExecArg in which we take common factors from arguments with more than one term. We allow only symbols as this code is used for the polyratfun only. We have a special routine, because the generic TakeContent does too much work and speed is at a premium here. Input: in is the input expression as a sequence of terms. Output: term: the content return value: the contentfree expression. it is in new allocation, made by TermMalloc. (should be in a TermMalloc space?)

4.119.2.20 GCDclean()

```
void GCDclean (
             PHEAD WORD * num,
             WORD * den )
```

Definition at line 2703 of file ratio.c.

4.119.2.21 PolyDiv()

```
WORD * PolyDiv (
             PHEAD WORD * a,
             WORD * b,
             char * text )
```

Definition at line 2800 of file ratio.c.

4.119.2.22 DIVfunction()

```
int DIVfunction (
             PHEAD WORD * term,
             WORD level,
             int par )
```

Definition at line 2847 of file ratio.c.

4.119.2.23 MULfunc()

```
WORD * MULfunc (
             PHEAD WORD * p1,
             WORD * p2 )
```

Definition at line 3020 of file ratio.c.

4.119.2.24 ConvertArgument()

```
WORD * ConvertArgument (
             PHEAD WORD * arg,
             int * type )
```

Definition at line 3083 of file ratio.c.

4.119.2.25 ExpandRat()

```
int ExpandRat (
             PHEAD WORD * fun )
```

Definition at line 3179 of file ratio.c.

4.119.2.26 InvPoly()

```
int InvPoly (
              PHEAD WORD * inpoly,
              WORD maxpow,
              WORD sym )
```

00137
00138 /*
00139         #] RatioFind :
00140         #[ RatioGen :
00141
00142         The algorithm:
00143         x1^-n1*x2^n2    ==>  x2 --> x1 + x3
00144         x1^n1*x2^-n2    ==>  x1 --> x2 - x3
00145         x1^-n1*x2^-n2   ==>
00146
00147            +sum(i=0,n1-1){(-1)^i*binom(n2-1+i,n2-1)
00148                    *x3^-(n2+i)*x1^-(n1-i)}
00149            +sum(i=0,n2-1){(-1)^(n1)*binom(n1-1+i,n1-1)
00150                    *x3^-(n1+i)*x2^-(n2-i)}
00151
00152         Actually there is an amount of arbitrariness in the first two
00153         formulae and the replacement x2 -> x1 + x3 could be made 'by hand'.
00154         It is better to use the nontrivial 'minimal change' formula:
00155
00156         x1^-n1*x2^n2:   if ( n1 >= n2 ) {
00157                            +sum(i=0,n2){x3^i*x1^-(n1-n2+i)*binom(n2,i)}
00158                         }
00159                         else {
00160                             sum(i=0,n2-n1){x2^(n2-n1-i)*x3^i*binom(n1-1+i,n1-1)}
00161                            +sum(i=0,n1-1){x3^(n2-i)*x1^-(n1-i)*binom(n2,i)}
00162                         }
00163         x1^n1*x2^-n2:   Same but x3 -> -x3.
00164
00165         The contents of the AT.TMout/params array are:
00166         length,type,x1,x2,x3,n1,n2
00167
00168 */
00169

01130
01131     Finds the GCD of the two arguments which are buffers with terms.
01132     In principle the first buffer can have only one term.
01133
01134     If both buffers have more than one term, we need to replace all
01135     non-symbolic objects by generated symbols and substitute that back
01136     afterwards. The rest we leave to the powerful routines.
01137     Philosophical problem: What do we do with GCD_(x/z+y,x+y*z) ?
01138
01139     Method:
01140     If we have only negative powers of z and no positive powers we let
01141     the EXTRASYMBOLS do their job. When mixed, multiply the arguments with
01142     the negative powers with enough powers of z to eliminate the negative powers.
01143     The DENOMINATOR function is always eliminated with the mechanism as we
01144     cannot tell whether there are positive powers of its contents.

03635
03636     The input polynomial is represented as a sequence of terms in ascending
03637     power. The first coefficient is 1. If we call this 1-a and
03638     a = sum_(j,1,n,x^j*a(j)), and b = 1/(1-a) we can find the coefficients
03639     of b with the recursion
03640         b(0) = 1, b(n) = sum_(j,1,n,a(j)*b(n-j))
03641     The variable is the symbol sym and we need maxpow powers in the answer.
03642     The answer is an array of pointers to the coefficients of the various
03643     powers as rational numbers in the notation signedsize,numerator,denominator
03644     We put these powers in the workspace and the answer is in AT.pWorkSpace.
03645     Hence the return value is an offset in the pWorkSpace.
03646     A zero pointer indicates that this coefficient is zero.

4.121.1 Detailed Description

This file contains the numerical routines. The arithmetic in FORM is normally over the rational numbers. Hence there are routines for dealing with integers and with rational of 'arbitrary precision' (within limits) There are also routines for that calculus modulus an integer. In addition there are the routines for factorials and Bernoulli numbers. The random number function is currently only for internal purposes.

              WORD * na,
              UWORD b )
```

Definition at line 1241 of file reken.c.

4.121.3.18 RaisPowCached()

```
void RaisPowCached (
              PHEAD WORD x,
              WORD n,
              UWORD ** c,
              WORD * nc )
```

Computes power x^n and caches the value

4.121.4 Description

Calculates the power x^n and stores the results for caching purposes. The pointer c (i.e., the pointer, and not what it points to) is overwritten. What it points to should not be overwritten in the calling function.

4.121.5 Notes

- Caching is done in AT.small_power[]. This array is extended if necessary.

Definition at line 1309 of file reken.c.

Referenced by poly::divmod_heap(), poly::divmod_univar(), and poly::mul_heap().

4.121.5.1 RaisPowMod()

```
WORD RaisPowMod (
              WORD x,
              WORD n,
              WORD m )
```

Definition at line 1396 of file reken.c.

4.121.5.2 NormalModulus()

```
int NormalModulus (
              UWORD * a,
              WORD * na )
```

Brings a modular representation in the range -p/2 to +p/2 The return value tells whether anything was done. Routine made in the general modulus revamp of July 2008 (JV).

Definition at line 1416 of file reken.c.

Referenced by AddCoef(), and MergePatches().

4.121.5.3 MakeInverses()

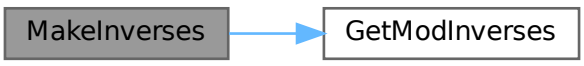
```
int MakeInverses (
              void  )
```

Makes a table of inverses in modular calculus The modulus is in AC.cmod and AC.ncmod One should notice that the table of inverses can only be made if the modulus fits inside a single FORM word. Otherwise the table lookup becomes too difficult and the table too long.

Definition at line 1453 of file reken.c.

References GetModInverses().

Here is the call graph for this function:



4.121.5.4 GetModInverses()

```
int GetModInverses (
              WORD m1,
              WORD m2,
              WORD * im1,
              WORD * im2 )
```

Input m1 and m2, which are relative prime. determines a∗m1+b∗m2 = 1 (and 1 is the gcd of m1 and m2) then a∗m1 = 1 mod m2 and hence im1 = a. and b∗m2 = 1 mod m1 and hence im2 = b. Set m1 = 0∗m1+1∗m2 = a1∗m1+b1∗m2 m2 = 1∗m1+0∗m2 = a2∗m1+b2∗m2 If everything is OK, the return value is zero

Definition at line 3550 of file reken.c.

4.121.5.25 NextPrime()

```
WORD NextPrime (
              PHEAD WORD num )
```

Gives the next prime number in the list of prime numbers.

If the list isn't long enough we expand it. For ease in ParForm and because these lists shouldn't be very big we let each worker keep its own list.

The list is cut off at MAXPOWER, because we don't want to get into trouble that the power of a variable gets larger than the prime number.

02227 */
02228 #else
02229
02230 /*
02231     New routine for GcdLong that uses smart shortcuts.
02232     Algorithm by J. Vermaseren 15-nov-2006.
02233     It runs faster for very big numbers but only by a fixed factor.
02234     There is no improvement in the power behaviour.
02235     Improvement on the whole of hf9 (multiple zeta values at weight 9):
02236         Better than a factor 2 on a 32 bits architecture and 2.76 on a
02237         64 bits architecture.
02238     On hf10 (MZV's at weight 10), 64 bits architecture: factor 7.
02239
02240     If we have two long numbers (na,nb > GCDMAX) we will work in a
02241     truncated way. At the moment of writing (15-nov-2006) it isn't
02242     clear whether this algorithm is an invention or a reinvention.
02243     A short search on the web didn't show anything.
02244
02245     31-jul-2007:
02246     A better search shows that this is an adaptation of the Lehmer-Euclid
02247     algorithm, already described in Knuth. Here we can work without upper
02248     and lower limit because we are only interested in the GCD, not the
02249     extra numbers. Also it takes already some features of the double
02250     digit Lehmer-Euclid algorithm of Jebelean it seems.
02251
02252     Maybe this can be programmed slightly better and we can get another
02253     few percent speed increase. Further improvements for the asymptotic
02254     case come from splitting the calculation as in Karatsuba and working
```

```
02255     with FFT divisions and multiplications etc. But this is when hundreds
02256     of words are involved at the least.
02257
02258     Algorithm
02259
02260     1: while ( na > nb || nb < GCDMAX ) {
02261         if ( nb == 0 ) { result in a }
02262         c = a % b;
02263         a = b;
02264         b = c;
02265        }
02266     2: Make the truncated values in which a and b are the combinations
02267        of the top two words of a and b. The whole numbers are aa and bb now.
02268     3: ma1 = 1; ma2 = 0; mb1 = 0; mb2 = 1;
02269     4: A = a; B = b; m = a/b; c = a - m*b;
02270        c = ma1*a+ma2*b-m*(mb1*a+mb2*b) = (ma1-m*mb1)*a+(ma2-m*mb2)*b
02271        mc1 = ma1-m*mb1; mc2 = ma2-m*mb2;
02272     5: a = b; ma1 = mb1; ma2 = mb2;
02273        b = c; mb1 = mc1; mb2 = mc2;
02274     6: if ( b != 0 && nb >= FULLMAX ) goto 4;
02275     7: Now construct the new quantities
02276         ma1*aa+ma2*bb and mb1*aa+mb2*bb
02277     8: goto 1;
02278
02279     The essence of the above algorithm is that we do the divisions only
02280     on relatively short numbers. Also usually there are many steps 4&5
02281     for each step 7. This eliminates many operations.
02282     The termination at FULLMAX is that we make errors by not considering
02283     the tail of the number. If we run b down all the way, the errors combine
02284     in such a way that the new numbers may be of the same order as the old
02285     numbers. By stopping halfway we don't get the error beyond halfway
02286     either. Unfortunately this means that a >= FULLMAX and hence na > nb
02287     which means that next we will have a complete division. But just once.
02288     Running the steps 4-6 till a < FULLMAX runs already into problems.
02289     It may be necessary to experiment a bit to obtain the optimum value
02290     of GCDMAX.

02902         #[ MakeLongRational:
02903
02904         Converts the long number a mod m into the fraction b
02905         One of the properties of b is that num,den < sqrt(m)
02906         The algorithm: Start with:   m 0
02907                                      a 1
02908         Make now c=m%a, c1=m/a       c c2=0-c1*1
02909         Make now d=a%c  d1=a/c       d d2=1-d1*c2
02910         Make now e=c%d  e1=c/d       e e2=1-e1*d2
02911             etc till in the first column we get a number < sqrt(m)
02912             We have then f,f2 and the fraction is f/f2.
02913         If at any moment we get a zero, m contained an unlucky prime.
02914
02915         Note that this can be made a lot faster when we make the same
02916         improvements as in the GCD routine. That is something for later.
